NJ GREEN HOME REMODELING GUIDELINES
Use of the Guidelines

What are the guidelines and what are they not?

The information provided in these guidelines is intended to assist homeowners, contractors, architects, interior designers, landscape architects, and other professionals who design and remodel residential structures. They draw upon best practices and provide a general overview of green remodeling strategies customized for New Jersey, with links to additional information and resources. These guidelines introduce ways a homeowner or remodeling professional can incorporate green building practices into common home remodeling projects. These are not step-by-step technical guides but rather a menu of ‘best practices’ organized by major building systems. One should become familiar with local building code and zoning requirements before undertaking a green home remodeling project.

The guidelines do not list or endorse specific green products or services but rather identify ‘greener’ options to consider when selecting materials and services for the home.

These Guidelines do not constitute an endorsement, approval, or recommendation of any kind by any persons or organizations affiliated with developing these Guidelines. The NJDEP further disclaims any and all liability for any personal injury, property damage or any other damages that are caused by or that may result from the reliance on these NJ Green Home Remodeling Guidelines.
Acknowledgments

The development of the New Jersey Green Home Remodeling Guidelines (NJGHRG) Version 1.0 was funded by the New Jersey Department of Environmental Protection (NJDEP) and the U.S. Environmental Protection Agency (USEPA), who contributed a grant for workshops and other marketing activities. Special thanks to Martin Rosen, NJDEP Office of Planning and Sustainable Communities, for his role as project manager.

The Rutgers Center for Green Building developed the guidelines with extensive input and review by an expert advisory group comprised of residential building and remodeling professionals, interior designers, landscape architects, and experts in the field of green building and energy-efficient design. The engagement of local expertise and real-life project examples were key to customizing the guidelines to New Jersey and providing insight into local opportunities, costs, and challenges.

Special thanks to the many individuals for contributing to the development of NJGHRG Version 1.0:

Introduction

Green Home Remodeling and Sustainability

What is green home remodeling and why is it important?

Residential buildings account for 22 percent of total energy and 74 percent of water consumed in the United States. When they contribute to climate change, the electricity used is generated from non-renewable and carbon-based fuels. A typical home emits almost 9,000 pounds of carbon dioxide* per person per year; altogether, residences contribute 17 percent of the nation’s carbon dioxide emissions. Moreover, Americans spend 90 percent of their time indoors, where concentrations of pollutants are often much higher than outside, making “green” in the residential sector important for both the environment and human health.

Within the menu of residential green practices, remodeling an existing home may be one of the most resource-efficient actions that a homeowner can take. Green home remodeling offers the opportunity to cost-effectively reduce home energy demand, reduce home maintenance costs, and increase occupant comfort and indoor air quality.

By taking advantage of pre-existing water, sewer, and road infrastructure, green home remodeling expands upon the inherent environmental benefits of remodeling with increased energy and water conservation, enhanced indoor air quality, reduced material waste and resource consumption, and the use of environmentally friendly products.

The basic principles of green remodeling are similar to those used in new green home construction. A major difference is that green home remodeling begins with an existing set of parameters that pose unique challenges and opportunities for employing green building strategies. Green construction of new homes can start with a blank slate of possibilities. However, it is the opportunity to green the nation’s existing housing stock that offers the most promising opportunity to meet current greenhouse gas emission targets and environmental goals.

Green Home Remodeling in New Jersey

Why is green home remodeling important for New Jersey?

New Jersey is the most developed state in the nation—and not by a little bit. The Garden State leads its nearest competitor in this category, Rhode Island, by about 25 percent. Although opportunities for infill and brownfield redevelopment exist, New Jersey could be the first state to reach full build-out of its remaining developable lands in just 20 to 40 years at the current pace of development and preservation. While this development trend leaves a shrinking window of opportunity to construct new green homes, it offers a growing opportunity to employ green remodeling strategies in existing homes.

An analysis done by the Rutgers Center for Green Building shows that the majority of the state’s housing stock is single-family detached housing built between 1940 and 1979. Houses need to be updated and remodeled 20 to 30 years after they are built, when major systems start to require upgrading or replacement. Therefore, the average age of the housing stock in New Jersey makes it an ideal candidate for green home remodeling. As fuel prices rise, homeowners in the state will greatly benefit from renovations that include the installation of energy-efficient appliances, efficient heating and cooling systems, and a better insulated building envelope.

At the national level, replacement projects that boost curb appeal – siding, windows, and decks – and kitchen remodels have been found to offer the best payback for homeowners (see Top 10 Project Paybacks for 2008, to the right). Given the recent real estate market, rather than buying a new house, many New Jersey homeowners may choose to stay put and remodel their homes.

The state’s environmental goals and recent commitments to cut greenhouse gas emissions, to invest in renewable energy, and to create green jobs further advances green home remodeling in the state.

*Green building terms are highlighted in bold and defined in a glossary at the back of each chapter.

Top 10 Project Paybacks for 2008

1. Upscale fiber cement siding (86.7%)
2. Midrange wood deck (81.8%)
3. Midrange vinyl siding (80.7%)
4. Upscale foam-backed vinyl (80.4%)
5. Midrange minor kitchen remodel (79.5%)
6. Upscale vinyl window replacement (79.2%)
7. Midrange wood window replacement (77.7%)
8. Midrange vinyl window replacement (77.2%)
9. Upscale wood window replacement (76.5%)
10. Midrange major kitchen remodel (76.0%)

A main goal of green remodeling is to reuse existing assets and limit the impact of the built environment on the natural environment. In this way, green remodeling helps to meet New Jersey’s planning goal to prevent urban sprawl and preserve natural resources and open space. The use of energy-efficient and renewable technologies can lower energy consumption by 30-50 percent annually, reduce utility bills and decrease demand on electrical power plants. This green strategy advances the state's goals of preserving energy resources and encouraging the development of different housing types within the limits of available infrastructure.

Green homes consume less water than conventional homes through water-efficient appliances and by recycling water for irrigation and other uses. This helps to lower water bills and reduces costs associated with the adverse effects of stormwater runoff such as flooding and water pollution. This green strategy furthers the state's goals to preserve wetlands and prevent degradation of the environment.

Green home construction calls for high-quality and durable materials, which reduces consumption of resources, maintenance costs, and adds value to a home. Reusing materials reduces the burden on the state's landfills, helps preserve the architectural features of historic homes, and maintains and improves the character of established neighborhoods in the state. This green strategy supports the state's goal to preserve the historical heritage of the region.

Green home building and remodeling reduces greenhouse gas emissions and curbs climate change. Almost all residential greenhouse gas emissions are related to energy consumption. Green home remodeling strategies that focus on energy efficiency help to reduce a home's carbon footprint. In turn, green home remodeling supports New Jersey's goal to reduce greenhouse gas emissions by 20 percent to 1990 levels by 2020, followed by further reductions of emissions to 80 percent below 2006 levels by 2050.

Development of the Guidelines

Why do we need the New Jersey Green Home Remodeling Guidelines?

Nationally, many states and local governments have recognized the need for green building and created programs and guidelines focused primarily on new green building, while offering some tips and techniques for green home remodeling. Specific green remodeling guidelines and certification programs are only now emerging, and several states have programs or are developing them. With no centralized national programs to certify green home remodeling projects, the United States Green Building Council (USGBC) partnered with the American Society of Interior Designers (ASID) to develop the REGREEN Residential Remodeling Guidelines 2008. Even though there are a growing number of green remodeling guidelines, books, websites, and magazines, many builders and homeowners are overwhelmed by the amount of information available and have no idea where to start. The New Jersey Green Home Remodeling Guidelines simplifies the process by highlighting strategies for remodeling homes of different ages and styles located in unique bio-regions of New Jersey. They draw on local expertise and examples and take into account the availability of materials, products, and services. The Guidelines recognize the local factors that influence the cost and feasibility of recommended green strategies and technologies, providing a customized roadmap with tips and knowledge not available in other state or national guidelines.

Role of the Expert Advisory Group

What was the process and who was involved in the development of the guidelines?

To gain a better understanding of the challenges and opportunities for green home remodeling in New Jersey, the RCGB conducted an analysis of the state's existing housing stock. Data gathered from the U.S. Census on housing unit type and age of structure showed the majority of the housing stock in rural and suburban counties of the State to be of single-family detached units built between 1940 and 1979. The Center also conducted a literature review to examine similarities and differences as well as applicability to New Jersey of several nationally recognized green home remodeling guidelines and programs.

The RCGB created an Expert Advisory Group in the spring of 2008 to inform the development of the guidelines. Meetings held during the course of the 16-month project and ongoing e-mail communication gathered the group's feedback and advice. Working groups matched expertise with the development of specific areas of the guidelines. Many of the case studies featured in the guidelines were either projects or...
recommendations from members of the Expert Advisory Group. The engagement of local expertise and real-life project examples were key to customizing the guidelines to New Jersey and providing insight into local opportunities, costs, and challenges.

**Relation to the REGREEN Residential Remodeling Guidelines 2008**

*How have the REGREEN guidelines inspired and informed the New Jersey Green Home Remodeling Guidelines?*

Concurrent with our launch of this project, the U.S. Green Building Council (USGBC) and the American Society of Interior Designers (ASID) unveiled the first draft of the REGREEN Residential Guidelines 2008 (www.regreenprogram.org). This opened an opportunity for the Rutgers Center for Green Building to benefit from national-level research on green home remodeling and customize recommendations for New Jersey.

The USGBC and ASID granted the RCGB the right to use the REGREEN strategy titles and strategy identification system (ID’s) to establish a formal link to the REGREEN guidelines. The *New Jersey Green Home Remodeling Guidelines (NJGHRG) Version 1.0* encompasses the REGREEN strategies deemed significant for New Jersey as well as strategies not covered by the REGREEN Guidelines. In most cases the REGREEN strategy titles were revised or combined to better reflect the purposes of the *NJGHRG*. In all cases, the strategy descriptions reflect original research conducted by the RCGB and the Expert Advisory Group. Furthermore, the *NJGHRG* draw on some of the design and organizational features of REGREEN but incorporate original photos and illustrations, use regional case study examples and present local resources and references where possible.

This collaborative partnership between the USGBC and ASID and the RCGB provides a model for how to adapt REGREEN to a regional (state) scale.

**Notes**

1. The Global Warming Response Act (GWRA) (P.L. 2007, c. 112) calls for reducing GHG emissions to 1990 levels by 2020, approximately a 25 percent reduction below estimated 2020 business-as-usual (BAU) emissions, followed by a further reduction of emissions to 80 percent below 2006 levels by 2050.

3. Ibid.
How to Use the Guidelines

Organization of the Guidelines

The Guidelines are organized into chapters by major project type: Kitchen, Bath and Living Spaces, Finished Basement and Major Addition, Weatherization and Energy, and Outdoor Living and Landscaping.

Each chapter includes the following:
- How to Use the Guidelines
- Health and Safety
- Green Home Maintenance and Housekeeping
- Best Practice Strategies
- Resources and References
- Case Studies
- Green Products and Services
- Glossary of Terms

Getting the Most from the Strategy Write-ups

The Guidelines provide information on best practice strategies for each project type. These strategy write-ups are organized by building system and follow the order of the 2008 REGREEN Residential Remodeling Guidelines (i.e., IDP2), which are incorporated with permission. Figure 1 describes the information available.

Title and REGREEN Strategy ID – The strategies in the REGREEN Residential Remodeling Guidelines 2008 inspired most of the strategies in these Guidelines. Where appropriate, the strategy references the related REGREEN strategy ID.

Shopping Cart – The cart \(\text{Shopping Cart}\) denotes entries in the Green Product and Service Guide located in the back of each project chapter.

Strategy Description – This write-up provides an overview of each strategy and its environmental benefits.

Glossary Term – Acronyms and green building terms are highlighted in bold and defined in a glossary at the back of each chapter.
Call-out Boxes - The call-out boxes in Figure 2 highlight information of special importance. These include the following types of information:

- **Tips** - useful hints or practical facts for accomplishing a strategy
- **Incentive** - sources of financial assistance
- **New Jersey Bio-Region** - New Jersey has 5 bio-regions, each with unique elements and environmental features to consider when remodeling
- **Building Age** - a home’s age can inform needed repairs and call out special circumstances
- **Caution** - on occasion, there are hazards associated, so items are called out for safety reasons

Hazard Symbol - Symbols were developed to advise users of certain health and safety threats related to specific strategies. The symbols, which appear below, reference the guidance on Health and Safety located at the beginning of each section.

- **HS1** – Nuisance and Toxic Dust Control
- **HS2** – Hazardous Materials - Asbestos & Lead
- **HS3** – Mold
- **HS4** – Radon

Web Link - When viewing this document electronically, the websites will hyperlink, however, occasionally website links change. In most cases, the site provides a seamless link to the new address. If this is not the case, users may need to copy and paste the link into the browser address bar. At the time of publication the hyperlinks in this report were all functional.

Scorecard - The scorecard, Figure 3, provides a snapshot of the environmental benefits, initial costs, and difficulty levels associated with a particular strategy. Both qualitative and quantitative information was used to assign scores to each strategy.

It is divided into two parts: 1) Benefits and 2) Feasibility.

Graphic icons were developed for each impact category.

**BENEFIT Key**

1 icon = low benefit, 2 icons = medium benefit, 3 icons = high benefit

**FEASIBILITY Key**

$ low initial cost, $$ medium initial cost, $$$ high initial cost

△ low difficulty level, ▲ medium difficulty level, ▲▲ high difficulty

The icons above have been developed to graphically describe the ratings that follow.

**BENEFITS**

**Energy Savings**

To help meet its greenhouse gas reduction responsibility, in 2007 New Jersey passed carbon dioxide (CO₂) reduction goals, i.e., achieve 1990 emission levels by 2020, followed by a further reduction of emissions to 80 percent below 2006 levels by 2050. The state has also established renewable energy and energy efficiency targets. Green remodeling strategies utilize renewable energy sources such as solar, geothermal, and wind to net a lower CO₂ footprint.
How to Use the Guidelines

Water Savings
Water conservation reduces water use both inside and outside the home. Within the home this may include low-flow fixtures. Outside the home this may refer to using native plants that have lower watering requirements or rain barrels to collect rainwater for reuse on the lawn and garden. Water management includes providing proper moisture control at footings, slab perimeter, and foundation walls as well as using porous paving materials to encourage stormwater recharge for reduced runoff.

Air Quality
Americans spend up to 90 percent of their time indoors where air quality can be more polluted than outdoors. Pollutants range from allergens such as mold, mildew, fungus, and dust mites to toxins, such as asbestos, and volatile organic compounds like formaldehyde and benzene found in building materials and a number of household items including pressed-wood furniture, computer ink, carpeting, and conventional household cleaners and cosmetics.

Resource Conservation
Resource conservation means using materials that are durable and easy to maintain with low embodied energy (the energy used in resource extraction, manufacturing, shipping). These come from renewable sources or are produced from waste, recycled materials, or salvaged from other uses. Avoiding building materials that deplete natural resources, such as old-growth timber, and materials made from toxic or hazardous substances improves nature’s ability to provide goods and services.

FEASIBILITY

$ Initial Cost
Cost is always a consideration for remodeling projects. Evaluating the cost of a recommended green remodeling strategy provides homeowners with a better sense of the relative costs and benefits of each recommended measure.

Costs come in two forms, so it is important to consider both in assessing feasibility. The first reflects initial costs of the strategy compared to conventional practices. A second consideration to make is the pay-back period or life-cycle cost. The pay-back costs are less obvious and are often project specific, but they can have significant environmental and economic value that factor into the overall cost. For more information on average costs, savings, and payback periods of typical energy efficiency improvements, see the Energy Efficient Rehab Advisor at (www.rehabadvisor.pathnet.org/). For customized results, have an energy professional conduct a thorough energy audit of your home.

$ Less than $500
$$ $500-$5,000
$$ $ Greater than $5,000

† Difficulty Level
Time is money and expertise is gained over time. Some people may consider a Home Performance Audit strategy in the ‘medium’ category because although relatively straightforward to act on, it requires experts with custom equipment to prepare an accurate assessment. Implementing the findings from a Home Performance Audit becomes a ‘high’ difficulty category as space heating and cooling systems, ventilation, water heating, appliances, climate and even site factors need to be integrated to assure desired energy improvements across ALL loads and to avoid negative unintended consequences. It is expected that ‘high’ difficulty strategies may also be dangerous for the basic homeowner to undertake.

† Easy to Do It Yourself (DIY) - little previous knowledge necessary
‡ Task for an Experienced DIYer or Professional - may require additional effort and higher learning curve than conventional strategy it replaces
‴ Task for an Expert/Certified Professional - high learning curve; new technique; requires specific green knowledge

10 Green Rules of Thumb

1. Start from where you are

Every home has a unique story and different starting point for going green. Greening an existing home is about more than just introducing a single green product or a collection of green technologies; it’s about how systems of the whole building work together to reduce environmental impacts. First, determine what makes sense for your home and your budget. Many of the most significant opportunities for reducing the environmental impact of a residential remodeling project lie in the decisions made at the very start of the project. Start with diagnostic tests such as a Home Performance Audit (Blower Door Test, infrared imaging, etc.) to uncover problem areas and discover opportunities for improvements and savings.

For more information on free and reduced-rate home performance energy audits, visit the New Jersey Clean Energy Office’s website, www.njcleanenergy.com/

2. Expand your definition of cost

When undertaking a green remodeling project, it is important to focus on long-term savings, ease of maintenance and resource conservation. The initial cost only provides one of the true cost of a product or design; a higher price can mean a better deal in the long run. For example, resource-efficient fixtures may cost more up front but save money over time by lowering monthly utility bills. Durable materials save money by requiring less frequent replacement. A low purchase price may simply mean a good deal—or it may signify a lack of quality or durability. It may also mean that some environmental, health or social costs are not reflected on the price tag.

The cost and design of construction services might seem expensive if only the up-front costs are considered. The actual cost comes when the benefits are included, which reflects savings in operation and maintenance. The collaborative nature of the green design approach requires more up-front time (which usually translates into billable hours), but this early planning stage means tremendous benefits later: design solutions that better meet a homeowner’s needs or reduce the project scope, fewer construction materials and expenses, or features that save energy, water, or maintenance.

For items that may increase your initial costs during construction, be sure to calculate the return on investment – the period of time it takes to realize the savings for items such as solar panels or added insulation. For information on Return on Investment for common green home remodeling strategies, see www.GreenandSave.com/master_roi_table.html

3. Reuse materials, reduce waste, and rethink space

Consider the 3-Rs: reduce, reuse, recycle. In green remodeling, the 3-Rs start at the earliest stages of design. By thinking creatively about how to reduce waste. Try to reuse as much as possible of the structure, finishes and furnishings. Keep in mind, though, that sometimes it makes sense to replace items, such as old, inefficient refrigerators with new energy-saving models. The size of your remodel will determine the resources to build it and maintain it. Before tearing down walls, think about how to reutilize existing rooms or consider opportunities to relocate space-constrained activities to outdoor spaces. If demolition is unavoidable, plan for deconstruction – or manually unbuilding and salvaging building materials – to help keep useable materials out of landfills.

Materials salvaged from deconstruction can be used on the current project, sold or donated. Develop a plan for recycling construction and demolition waste. Close the loop by choosing new materials that have a High-Recycled Content.

Look for salvaged materials at demolition sales and local salvage stores such as Habitat for Humanity ReStores (www.habitat.org/env/restores.aspx) and Goodwill Retail Stores (www.locator goodwill.org/), or through websites like www.Craigslist.org and www.FreeCycle.org.

4. Conserve energy and use the sun

The energy used to heat, cool and power homes pollutes the atmosphere and contributes to global climate change. Additionally, inefficient homes are costly to maintain. A first step in any green remodeling project involves making homes as energy-efficient as possible and then relying on sources of clean and renewable energy for any remaining energy demands.

The sun provides free and plentiful energy in the form of daylight and heat. Although it is easier to incorporate passive solar techniques when building a brand-new home, every remodeling project should also be evaluated to identify passive solar opportunities.

- Insulate the building to a very high level and reduce infiltration to prevent heat loss.
- Consider the orientation of the home or addition at the start of any project. South-facing walls and windows will receive the most sunlight. Design roof overhangs for south-facing windows to let sun in during the winter and keep sun out in the summer.
- Use wall and floor materials with thermal mass to absorb heat and cold.
- Incorporate awnings, trellises and deciduous shade trees to limit summertime solar heat gain through south-, east- and west-facing windows.
- Design windows and operable skylights to catch prevailing breezes and provide natural ventilation.
- Reduce solar heat gain by using light exterior colors or paints with reflective pigments, ENERGY STAR® roofing materials, and/or radiant barrier roof sheathing.

**Conserve water and gather rain**

New Jersey has abundant water resources—so why worry about saving water? Aside from periodic droughts, the simplest answer is that conserving water saves money. If household water is supplied by a well and septic system, conserving water can extend the life of the system and delay the need for repair.

If a home is serviced by a municipal water system, the less water that it uses, the smaller the bill. Conserving water can also reduce energy bills lowering water heating costs. Most people use approximately 50–75 gallons of water indoors every day, with up to 75 percent of that used in the bathroom.

According to the EPA, a typical single-family suburban household uses at least 30 percent of their water outdoors for irrigation. Some experts estimate that more than 50 percent of landscape water use goes to waste from evaporation or runoff caused by over watering. Install faucet aerators and low-flow fixtures to reduce water use indoors and consider using a rain barrel or rain garden to water native plants in the garden.

For more information on how to save water in the home, visit the U.S. EPA WaterSense website, [www.epa.gov/watersense/](http://www.epa.gov/watersense/).

For up-to-date information on low-flow toilet performance tests, visit the California Urban Water Conservation Council website, [www.cuwcc.org/maptesting.aspx](http://www.cuwcc.org/maptesting.aspx).

**Consider the life-cycle of products and materials**

“The greenest home is the one that is already built”

— National Trust for Historic Preservation

Everything — every material, every product — has a life cycle. A life cycle is the journey a material goes through from its raw form through processing to a finished product. All the energy to extract, process, manufacture, transport, and install a product is called its ‘embodied energy’. When a home is demolished and landfilled, the energy locked up in it is totally wasted. Demolition itself uses energy and, of course, the construction of a new home in place of the demolished one uses more energy and resources yet.

<table>
<thead>
<tr>
<th>Embodied Energy of Materials and Construction per square foot of Construction*</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Residential – Single Family</td>
<td>700 MBTU/sq. ft.</td>
</tr>
<tr>
<td>Residential – 2 to 4 Family</td>
<td>630 MBTU/sq. ft.</td>
</tr>
<tr>
<td>Residential – Garden Apartment</td>
<td>650 MBTU/sq. ft.</td>
</tr>
</tbody>
</table>

To calculate the embodied energy of your home, take the Embodied Energy Survey developed by The Greenest Building Organization at [www.thegreenestbuilding.org/survey.html](http://www.thegreenestbuilding.org/survey.html).

Try to follow these guidelines:

- Design for long life and adaptability, using durable low maintenance materials.
- Ensure materials from construction and demolition wastes are reused or recycled.
- Use locally sourced materials (including materials salvaged on-site) to reduce transport.
- Select low-embodied energy materials (which may include materials with a high-recycled content).
- Select materials that can be reused or recycled easily at the end of their lives using existing recycling systems.
- Give preference to materials manufactured using renewable energy sources.
- Use efficient building envelope design and fittings to minimize materials (e.g., an energy-efficient building envelope can downsize or eliminate the need for a large HVAC system).

For more information on preserving a home’s embodied energy as well as its historic features, visit the National Trust for Historic Preservation’s website on sustainability: [www.preservationnation.org/issues/sustainability/](http://www.preservationnation.org/issues/sustainability/)

**Avoid Toxins**

The United States Environmental Protection Agency (USEPA) reports that the air in homes can be 5-10 times more polluted than outdoor air. According to research published in the *New England Journal of Medicine*, 40 percent of children will develop respiratory disease in part due to the chemicals in their homes. To minimize exposure, select products and furnishings for the home that do not contain volatile organic compounds (VOCs), flame retardants, and formaldehyde. The Washington Toxics Coalition (WTC) reports that using entryway mats can reduce the amount of dust on carpets by 33 percent. And homes where shoes are removed at the door, according to the WTC, have 10 times less dust than homes where shoes are worn.

Leading causes of poor indoor air quality include:

- Off-gassing of chemicals from building products and materials
- Combustion by-products from open-flame appliances
- Lead dust from old paint
- Asbestos from old insulation, floor tiles, siding or fireproofing
- Dust mites and other biological pollutants like dander and pollens
- Mold caused by excess moisture and/or poor ventilation
- Radon that migrates from soil into the house

For more information on ways to reduce exposure to toxics in the home, see the Health and Safety section in this guideline or visit the American Lung Association’s Health House website: [www.healthhouse.org/](http://www.healthhouse.org/)

**Connect to Nature**

Disturbing or removing vegetation causes a site to lose valuable ecosystem services such as climate regulation, protection of soil health, provision of habitat for wildlife and pollinators, and filtration of pollutants from water and air. This also can restrict the capacity of
the landscape to intercept and infiltrate water which in turn manages stormwater, recharges groundwater and filters water. Furthermore, studies show that the visual effects of flowers and plants are good for people. A Chicago study links tree and grass cover to fewer property crimes, fewer violent crimes, stronger ties between neighbors, more frequent use of common neighborhood spaces and a greater sense of safety. During construction, avoid cutting down existing trees and disturbing vegetation. Keep in mind that well-designed landscapes promote biodiversity with a mix of native species and ecologically appropriate non-native species.

For more information on creating sustainable sites, see the Sustainable Sites Initiative website (www.sustainablesites.org) or check out the National Wildlife Foundation’s Garden for Wildlife website (www.nwf.org/gardenforwildlife).

Communicate Green Remodeling Priorities

A successful green remodeling project requires homeowners, interior designers, architects, engineers, builders, and trade contractors to coordinate their efforts as early as possible. To make sure that everyone understands and to hold them accountable for the green features of the project the following two steps are essential:

1. Incorporate green items directly into the specifications for the projects.
2. Attach a green remodeling checklist to the blueprints to make it easier for everyone involved—including the building professionals, homeowner and municipality—to see which green features are included in the remodeling project.

For tips on hiring and working with design professionals and contractors when working on green remodel projects, check out Seattle’s Green Home Remodeling “Hiring a Pro” guide book: www.seattle.gov/dpd/cms/groups/pan/@pan/@sustainableblding/documents/web_informational/dpds_007579.pdf.

Get Paid to Green Your Home

Homeowners can receive federal and state tax credits for installing energy-efficient windows, doors, roofing and insulation as well as furnaces, air conditioners and heat pumps. Details on qualifying improvements are updated regularly on the Database of State Incentives for Renewables and Efficiency (DSIRE) website, www.dsireusa.org/.

New Jersey electric and gas utilities also offer rebates for Energy Star® appliances and energy efficiency upgrades, as well as free online energy efficiency surveys for the home. Water utilities may offer free leak-detection services, free shower and faucet aerators, landscaping and water audits, and free or rebated toilets, dishwashers and clothes washers.

For more information, check with your local utility or the New Jersey Office of Clean Energy website, www.njcleanenergy.com/residential/home/home.

Notes:

NJDEP Clean Water NJ
www.cleanwaternj.org/index.htm
The contemporary home serves many different functions for both living and working. Today, best practice for remodeling these areas includes options that not only meet functional needs but are also highly effective in mitigating environmental impact. Kitchens and bathrooms are active spaces and significant consumers of water and energy; choosing environmentally friendly appliances, fixtures, and finishes helps to reduce energy and water consumption and protect non-renewable resources. In kitchens and especially bathrooms, it is advised to invest in durable, high performance features. Whether it’s through an energy-saving dishwasher, living room flooring made from renewable materials, bed linens made from bamboo, or a high-efficiency exhaust system, greening living spaces is a fundamental part of the overall green home remodel.
Kitchens, Bathrooms, and Living Spaces

How to Use the Guidelines

Health and Safety
- HS1 - Nuisance and Toxic Dust Control
- HS2 - Hazardous Materials - Asbestos & Lead
- HS3 - Mold
- HS4 - Radon

Green Home Maintenance and Housekeeping

Building Envelope
- Detail window sills in wet areas [IDP26]
- Seal and flash windows/skylights [IDP27]
- Upgrade or replace existing windows [EA56/59]
- Upgrade existing exterior door [EA57]
- Provide shading of skylights as needed [EA61]
- Isolate attached garages [IEQ165]

HVAC
- Use ceiling fans for natural ventilation [EA65]
- Install programmable thermostats [EA67]
- Make sure ductwork is clean [EA71]
- Install effective ventilation [IEQ166-167/172]
- Provide fresh air in ventilation system [IEQ171]
- Vent all combustion-based equipment [IEQ168]
- Install automatic shut-off on bathroom fans [IEQ167]

Lighting and Electrical
- Provide daylighting [EA83]
- Provide appropriate lighting [EA84]
- Install energy-efficient lighting [EA85]
- Provide controllable interior shading [IEQ178]

Wall and Ceiling
- Install eco-friendly interior sheathing [MR126]
- Select eco-friendly interior doors [MR127]
- Choose eco-friendly paints, sheens, and finishes [IEQ185/MR130-131]
- Consider tile with recycled content [MR132]
- Select eco-friendly wall coverings [MR129/IEQ186]
- Use non-paper-faced gypsum board in moist areas [IEQ183]
- Use low-VOC construction products [IEQ187]
- Avoid carpeting in moist areas [IEQ179]

Floors and Flooring Products
- Reuse existing flooring and subflooring [MR133]
- Choose hard, low-formaldehyde floors [IEQ180/MR134]
- Use reclaimed or renewable materials [MR135-136]
- Refinish floors with eco-friendly products [MR137]
- Select eco-friendly carpeting [IEQ182/MR139]

Plumbing
- Install water-saving fixtures [WE42-44]
- Install water filtration system [IEQ175-176]
- Include a plumbing access panel [MR123]
- Choose a high-efficiency water heater [EA79]
- Consider eco-friendly piping material [MR122]
- Reconfigure plumbing for efficiency [EA77]
- Install instantaneous hot water heater

Equipment
- Select high-efficiency clothes washer [EA92]
- Select an energy-efficient refrigerator [EA93]
- Choose an energy-efficient dishwasher [EA94]
- Install energy-efficient cooking appliances [EA95]
- Select energy-efficient office equipment [EA99]

Laundry
- Install single-throw shut-off valve [MR124]
- Install drain pan for clothes washer [MR125]
- Provide air-lock dryer vent [EA72]
- Minimize dryer duct lengths and turns [EA73]

Furniture and Fittings
- Select eco-friendly furniture [MR141-143/146-148/150]
- Select eco-friendly cabinetry and countertops [MR140/145/148-149]
- Support local craftsmen [MR153]
- Select furniture that is easy to clean [IEQ192]
- Select healthier window treatments [IEQ193]

Uses
- Use green cleaning materials/strategies [IEQ196]
- Regularly maintain equipment [EA91]
- Designate a built-in recycling center

Case Studies

Green Products and Services

Glossary of Terms
How to Use the Guidelines

Organization of the Guidelines

The Guidelines are organized into chapters by major project type: Kitchen, Bath and Living Spaces, Finished Basement and Major Addition, Weatherization and Energy, and Outdoor Living and Landscaping.

Each chapter includes the following:

- How to Use the Guidelines
- Health and Safety
- Green Home Maintenance and Housekeeping
- Best Practice Strategies
- Resources and References
- Case Studies
- Green Products and Services
- Glossary of Terms

Getting the Most from the Strategy Write-ups

The Guidelines provide information on best practice strategies for each project type. These strategy write-ups are organized by building system and follow the order of the 2008 REGREEN Residential Remodeling Guidelines (i.e., IDP2), which are incorporated with permission. Figure 1 describes the information available.

Title and REGREEN Strategy ID – The strategies in the REGREEN Residential Remodeling Guidelines 2008 inspired most of the strategies in these Guidelines. Where appropriate, the strategy references the related REGREEN strategy ID.

Shopping Cart – The cart denotes entries in the Green Product and Service Guide located in the back of each project chapter.

Strategy Description – This write-up provides an overview of each strategy and its environmental benefits.

Glossary Term – Acronyms and green building terms are highlighted in bold and defined in a glossary at the back of each chapter.
Call-out Boxes - The call-out boxes in Figure 2 highlight information of special importance. These include the following types of information:

- Tips - useful hints or practical facts for accomplishing a strategy
- Incentive - sources of financial assistance
- New Jersey Bio-Region - New Jersey has 5 bio-regions, each with unique elements and environmental features to consider when remodeling
- Building Age - a home’s age can inform needed repairs and call out special circumstances
- Caution - on occasion, there are hazards associated, so items are called out for safety reasons

Hazard Symbol - Symbols were developed to advise users of certain health and safety threats related to specific strategies. The symbols, which appear below, reference the guidance on Health and Safety located at the beginning of each section.

- HS1 – Nuisance and Toxic Dust Control
- HS2 – Hazardous Materials - Asbestos & Lead
- HS3 – Mold
- HS4 – Radon

Web Link - When viewing this document electronically, the websites will hyperlink, however, occasionally website links change. In most cases, the site provides a seamless link to the new address. If this is not the case, users may need to copy and paste the link into the browser address bar. At the time of publication the hyperlinks in this report were all functional.

Scorecard - The scorecard, Figure 3, provides a snapshot of the environmental benefits, initial costs, and difficulty levels associated with a particular strategy. Both qualitative and quantitative information was used to assign scores to each strategy.

It is divided into two parts: 1) Benefits and 2) Feasibility.

Graphic icons were developed for each impact category.

**BENEFIT Key**

1 icon = low benefit, 2 icons = medium benefit, 3 icons = high benefit

**FEASIBILITY Key**

$ low initial cost, $$ medium initial cost, $$$ high initial cost

† low difficulty level, ‡ medium difficulty level, ‡‡ high difficulty

The icons above have been developed to graphically describe the ratings that follow.

**BENEFITS**

Energy Savings

Energy efficiency reduces energy use in the home, reduces carbon dioxide (CO₂) emissions, and helps stem climate change. New Jersey passed aggressive CO₂ reduction goals to lower greenhouse gas emissions to 1990 levels by 2020. The 20 percent reduction is followed by a further reduction of emissions to 80 percent below 2006 levels by 2050. The state has also established renewable energy targets. Green remodeling strategies utilizing renewable energy sources such as solar, geothermal, and wind will net a lower CO₂ footprint.
Water Savings

Water conservation reduces water use both inside and outside the home. Within the home this may include low-flow fixtures. Outside the home this may refer to using native plants that have lower watering requirements or rain barrels to collect rainwater for reuse on the lawn and garden. Water management includes providing proper moisture control at footings, slab perimeter, and foundation walls as well as using porous paving materials to encourage stormwater recharge for reduced runoff.

Air Quality

Americans spend up to 90 percent of their time indoors where air quality can be more polluted than outdoors. Pollutants range from allergens such as mold, mildew, fungus, and dust mites to toxins, such as asbestos, and volatile organic compounds like formaldehyde and benzene found in building materials and a number of household items including pressed-wood furniture, computer ink, carpeting, and conventional household cleaners and cosmetics.

Resource Conservation

Resource conservation means using materials that are durable and easy to maintain with low embodied energy (the energy used in resource extraction, manufacturing, shipping). These come from renewable sources or are produced from waste, recycled materials, or salvaged from other uses. Avoiding building materials that deplete natural resources, such as old-growth timber, and materials made from toxic or hazardous substances improves nature's ability to provide goods and services.

FEASIBILITY

$ Initial Cost

Cost is always a consideration for remodeling projects. Evaluating the cost of a recommended green remodeling strategy provides homeowners with a better sense of the relative costs and benefits of each recommended measure.

Costs come in two forms, so it is important to consider both in assessing feasibility. The first reflects initial costs of the strategy compared to conventional practices. A second consideration to make is the pay-back period or life-cycle cost. The pay-back costs are less obvious and are often project specific, but they can have significant environmental and economic value that factor into the overall cost. For more information on average costs, savings, and payback periods of typical energy efficiency improvements, see the Energy Efficient Rehab Advisor at (www.rehabadvisor.pathnet.org/). For customized results, have an energy professional conduct a thorough energy audit of your home.

Less than $500
$500-$5,000
Greater than $5,000

Difficulty Level

Time is money and expertise is gained over time. Some people may consider a Home Performance Audit strategy in the ‘medium’ category because although relatively straightforward to act on, it requires experts with custom equipment to prepare an accurate assessment. Implementing the findings from a Home Performance Audit becomes a ‘high’ difficulty category as space heating and cooling systems, ventilation, water heating, appliances, climate and even site factors need to be integrated to assure desired energy improvements across ‘ALL loads’ and to avoid negative unintended consequences. It is expected that ‘high’ difficulty strategies may also be dangerous for the basic homeowner to undertake.

Easy to Do It Yourself (DIY) - little previous knowledge necessary

Task for an Experienced DIYer or Professional - may require additional effort and higher learning curve than conventional strategy it replaces

Task for an Expert/Certified Professional - high learning curve; new technique; requires specific green knowledge

Health and Safety

Green remodeling poses hazards typical of many other home renovation or remodeling projects because of the age of the homes (given that they are more likely to contain older and use more hazardous materials) and the incentive for green remodeling to replace older or damaged building systems.

New Jersey homeowners considering green remodeling should anticipate potential emissions of hazardous air contaminants during removal of old building materials. The risks associated with improper removal of materials containing asbestos, lead, mold or even fiberglass insulation are minimized by understanding and following the steps listed here prior to initiating work. For complex situations, consider hiring professionals.

General hazard recognition and risk reduction information for the following potential renovation-related risks are contained in this section:

- HS1 – Nuisance and Toxic Dust Control
- HS2 – Hazardous Materials - Asbestos & Lead
- HS3 – Mold
- HS4 – Radon

**HS1 – Nuisance and Toxic Dust Control**

Construction projects involving demolition of existing sheetrock, plaster, wood, brick or concrete products in ceilings, walls or floors of a home will release dust as these materials are ripped, sanded, ground, pulverized or crushed. Control of dust emissions during the pouring of solids or from transferring of small particles is controlled in industrial facilities. Homeowners planning renovation projects should also consider steps to minimize the release and maximize control of dust in the environment. These nuisance dusts, when released from the point of origin into the air of the home, tend to remain suspended in the air for very long periods of time, and as such, will be transported with air currents caused by open doors, cracks around and beneath doorways, forced air heating and cooling ductwork, and even by the air currents caused by persons walking in and out of dusty areas, to other areas of the home. At a minimum, allowing the uncontrolled release of nuisance dusts from any demolition project, as well as those created from sawing, sanding, or grinding of newly constructed materials (e.g., sheetrock, spackling, wood dust etc.) presents unnecessary and difficult dust cleanup demands for affected living spaces. At their worst, susceptible occupants of homes where uncontrolled nuisance dusts are allowed to escape into adjacent living spaces may temporarily experience eye, nose, or throat irritation. Asthmatics may experience adverse respiratory distress when exposed to high levels of nuisance dust particles.

There are several simple steps to minimize potential hazards of nuisance dust during remodeling.

1. Remove unnecessary porous and non-porous materials (e.g., draperies, bedding, upholstered furniture, children's toys, clothing, etc.) from the project area.
2. Seal the project area from the remainder of the home using polyethylene sheeting at doorways and at inlets to any forced air supply or return registers within the project space.
3. Consider installing HEPA filtered air scrubbers in the project area and discharging the exhaust air through an adjacent window using a tight fitting flexible duct through a sealed window opening (consider surrounding security requirements). Use a lightweight section of facial tissue at the doorways to confirm that air pressure is moving from the clean adjacent living space and into the project area (not the other direction) so that air leaks from the clean home into the dirty renovation area. This will reduce any potential for dusts from the renovation area to enter the adjacent areas of the home.
4. Periodically during the work session and after every work session, HEPA vacuum the renovation area following renovations to remove accumulated surface dust, without re-suspending it into the air.
When removing old building materials, know that they contain hazardous materials, which while intact present little to zero risk to occupants, but when removing can create airborne emissions and increase health and safety risks. This is especially true of asbestos and lead, and, possibly to a lesser extent, fiberglass. Removal of asbestos, lead or fiberglass needs to be planned and conducted with care to minimize exposures to airborne dust from these materials.

Asbestos

Asbestos is a mineral that has been mined in the U.S. since the early 1900’s. Its superior heat resistance properties, combined with its lightweight, high-tensile strength, and non-corrosive qualities, made it an ideal building material for buildings constructed between 1940 and the late 1980’s. Asbestos was banned as a building material in the U.S. after scientists concluded studies linking long-term occupational exposures to damaging respiratory health including asbestosis (scarring of the lung), lung cancer, and mesothelioma (cancer of the lining of the lung). Because intact asbestos presents no increased health risk, there is no requirement for removing it from existing homes. However, when it is disrupted, pulverized or suspended in air, the potential for inhalation of asbestos fibers increases risks of exposure. While health effects develop only after decades of long-term occupational or environmental exposure, homeowners should take particular care to prevent unintentional release of asbestos into the air of their homes during green remodeling efforts so that children and others are not exposed.

Asbestos is commonly found in older homes (constructed between 1940 and the late 1980’s) in the following building materials:

- Pipe and boiler insulation
- Sprayed on fireproofing insulation
- Acoustical tiles and wall coverings
- Floor tiles
- Roof shingles
- Siding shingles

There is no requirement that homeowners remove asbestos-containing materials from homes. However, if removal is part of a green building remodeling project, material should be tested by a New Jersey licensed asbestos control monitor, and if determined to contain asbestos, be removed by a New Jersey licensed asbestos contractor. The number of the state program to contact for assistance in identifying qualified personnel to assist homeowners to safely address any possible asbestos concerns is (609) 292-7837. General information about asbestos and its proper management and disposal can be found at the Department of Health website: www.state.nj.us/health/iep/asbestos.shtml and the Department of Environmental website: www.nj.gov/dep/dshw/rrtp/asbestos.htm.

Lead

Lead was in residential paints prior to 1978. It was banned after that time due to the significant health affects to children inhaling or consuming dusts from lead-based paints. Because of the hazards posed by dusts and chips of lead-painted surfaces, any remodeling or renovation which impacts painted surfaces of homes constructed prior to 1978 needs to be inspected by a New Jersey licensed lead inspector. If lead paint is identified, it should be safely removed by a state of New Jersey licensed contractor. They can safely remove lead-based paint and conduct follow-up surface lead testing to confirm that the removal was successful. Information on lead-based paint and qualifications for lead inspectors and contractors can be found at: www.state.NJ.us/health/iep/documents/pb_advisory_bulletin.pdf.

Contact the New Jersey Department of Health and Senior Services at (609) 292-7837 with any questions.

Fiberglass

Fiberglass insulation is a manufactured glass-wool-like material used as an insulation and sound absorption material in homes, schools, automobiles and consumer products since the 1970’s. Fiberglass insulation can be safely installed if handled properly; any prolonged skin, eye or respiratory contact with fiberglass can cause temporary irritation. During renovation, wear loose fitting clothing and gloves to reduce skin contact, eye glasses or goggles to reduce eye exposure, and N95 disposable respirators (available from any home improvement store) if high levels of fiberglass dust are expected during removal or installation. More information on fiberglass safety precautions and handling recommendations can be found at the American Lung Association website at: www.lungusa.org/site/pp.asp?c=dvLUK900E&b=35439 or call the American Lung Association in New Jersey at (908) 687-9340.
HS3 – Mold

Mold contamination of building materials is not limited to older homes. Homes of any age can develop mold if moisture from leaky pipes, roofs, foundations, accumulates in the presence of dust, wood, paper or other cellulose-containing materials at normal room temperatures or high relative humidity (76 percent) for as little as 48 hours. Standing moisture around building materials such as wallboard, carpets, insulation, wood or other cellulose containing materials can cause mold. Many mold spores are known human allergens and produce toxins which may cause irritation or central nervous system effects. Because of vast differences in susceptibility, or if individual health impacts related to elevated mold spore exposure are of concern, consult a trained and experienced occupational/environmental health physician.

In addition to the above, mold damage can occur if flooding from faucets, showers, toilets (above the trap), is not completely dried within 48 hours of the incident. Floods from dirty water sources such as washing machines, dishwashers or sewers may contain high levels of bacteria, viruses, and protozoa which, along with potential mold growth, present additional risks.

If mold amplification sites occur, remove the affected material using methods that prevents unintentional dispersal of mold spores and the source of moisture intrusion. The U.S. Environmental Protection Agency indicates that small areas of mold growth (less than 10 square feet) can be cleaned or removed by homeowners themselves using precautions to prevent exposure and reduce spread of spores to adjacent areas. When mold contaminated areas exceed 10 square feet, special precautions including erecting containment barriers and the use of specialized HEPA vacuum devices should be used by trained professionals. When mold contamination occurs in excess of 100 square feet, professionals need to clean using full containment of the area (see www.epa.gov/mold/moldguide.html).

If mold growth from dirty water floods occurs, take special precautions to prevent skin, eye, oral and inhalation contact, and hire trained professionals to clean up in accordance with U.S. EPA: www.epa.gov/iaq/flood/index.html and IICRC S500 guidelines

Homeowners should anticipate that the amount of mold contamination shown on the outside of a piece of drywall or paneling may be less than the amount that will be exposed when wall cavities are opened up. If there is any doubt, consider hiring a professional Certified Industrial Hygienist (CIH) to evaluate the extent of damage before attempting to remove contaminated building materials yourself.

HS4 – Radon

Radon is a radioactive gas that comes from the natural decay of uranium in the ground. It is odorless, tasteless and invisible, and can only be detected through specialized tests. Radon enters homes through openings such as cracks and joints in the foundation, sump pits and openings around pipes. The home traps radon inside and it can build up to high levels.

Radon is the second leading cause of lung cancer in the United States, resulting in 15,000 to 22,000 deaths annually. It is the leading cause of lung cancer for non-smokers.

Radon concentrations can vary from house to house. The radon concentration in a home depends on a number of factors, including the amount of uranium present in the soil, the permeability of the soil, the number of openings in the foundation and air pressure differentials. Any home can have a radon problem, regardless of whether it is old or new, well sealed or drafty, or with or without a basement.

The New Jersey Department of Environmental Protection recommends radon testing for all homes in New Jersey. If the radon concentration is 4 pCi/L or higher, a radon mitigation system is recommended. There is no safe level of radon since lung cancer can result from very low exposures to radon, however, the risk decreases as the radon concentration decreases. If the radon concentration is less than 4 pCi/L, a mitigation company can be consulted to determine whether the radon level can be brought down still further. Radon levels have been brought to less than 1 pCi/L in sixty percent of the homes mitigated in New Jersey. Mitigation systems can also help reduce the potential for accumulation of volatile organic compounds that may be released from soil water vapor in areas where ground water contamination is an issue.

Radon test kits are commercially available at most home improvement stores, however, test conditions and locations may make data interpretation difficult or inaccurate. Carefully follow the kit directions to ensure proper use and confidence in the results. The New Jersey Department of Environmental Protection has issued licensing requirements for radon testing firms, and has a list of qualified professionals to perform radon testing and mitigation, see www.njradon.org.

Green Home Maintenance and Housekeeping

Introduction

Your home is one of the biggest investments of your life. Can ‘going green’ protect your investment and make it safer, more enjoyable and save you money? Yes.

This guide to Green Home Maintenance and Housekeeping practices will improve the health, comfort and environment for your family, and save you money, most directly by reducing your utility bills. The guide’s focus on ‘Energy’ savings, improvements to ‘Indoor Air Quality’, effective and efficient ‘Household Waste Management’ and conserving ‘Water’ all add measurable benefits to you and high return on your investment.

Routine checks and repairs will ensure your home’s appearance and proper function. By following these recommendations, you will also prevent more expensive damage from occurring.

Kitchen, Bath & Living Spaces

Kitchen, bath and living spaces comprise the prime areas of your home - with maximum utility, and hence require regular upkeep.

1. Maximize natural ventilation and daylight
   - Keep windows (especially kitchen window) open for natural ventilation whenever possible
   - Take full advantage of natural daylight
   - Clean and maintain windows and doors to keep them weatherproof and in good working order
   - Use the exhaust fan (vented to the outside) when cooking

2. Use appliances efficiently and effectively
   - If your refrigerator is more than 10 years old, consider replacing it as new technology has dramatically improved its energy efficiency
   - Clean the refrigerator’s condenser coils twice a year
   - Clean the cooking range hood filter
   - Unplug appliances (like toaster, coffeemakers, etc..) when not in use.
   - Use microwave for quick food warming
   - Wash only full loads of dishes to save energy and water
   - Avoid the need for pre-rinse cycles by carefully scraping dishes before adding them to the load
   - Wash only full loads of laundry to save energy and water
   - Use cold water detergents to reduce the need for hot water laundry
   - Use a compost container instead of the garbage disposal to save energy and improve your garden soil

3. Minimize and dispose of waste appropriately - Reduce, Reuse, and Recycle
   - Provide easy access to and sufficient room for recyclables storage in the kitchen
   - Switch from disposable products to reusable products: food and beverage containers, cups, plates, writing pens, razors, towels, shopping bags, batteries, etc.
   - Instead of products that are packaged for single use, buy items in bulk and transfer to your own reusable containers
   - Buy recycled: resale shops offer good kitchen equipment at a fraction of retail costs
   - Sell or donate used goods instead of throwing them out
   - Recycle paper, yard trimmings, glass, aluminum, other metals, batteries, used motor oil, and plastics
   - Use canvas shopping bags
   - Use tap water in a reusable container instead of bottled water
Green Home Maintenance and Housekeeping

4. Prevent Water-related Problems
   • Use bathroom fans while showering and allow them to run for 20 to 30 minutes after showering (installing a timer will make this easier)
   • Fix leaky toilets and repair dripping faucets
   • Check traps and drains under sinks, tubs, showers for leaks
   • Keep a check on bathtub surrounds to avoid mold problems

5. Use water wisely
   • Shut off water when brushing or shaving
   • Take short showers instead of baths
   • Dispose of tissues and other similar waste in the trash rather than flushing unnecessarily
   • Use a broom instead of a hose to clean your driveway or sidewalk

6. Keep your family and your home free from pollutants and pests
   • Organic fertilizers and pest control will cut down on the pollutants tracked into your home
   • Keep an entry mat and encourage everyone to remove their shoes at the doorway
   • Mount carbon monoxide monitors in living spaces
   • Do not allow smoking in homes as it can be harmful for the children and other occupants
   • Use non-toxic, biodegradable cleaners; vinegar and baking soda are among the most common (and cheapest!) recommended substitutes – and plain soap is still the cheapest effective disinfectant
   • Minimize the use of chemical formulations by cleaning surfaces and floors with soap and water along with additives such as lemons, vinegar and baking soda
   • Do not pour toxic cleaning products down the drain
   • Clean clogged drains with boiling water followed by baking soda and vinegar
   • Use a snake or a plunger for difficult clogs instead of toxic drain cleaners
   • Keep the kitchen counters, floor surfaces and stovetops clean to control pests (rodents, termites, roaches, etc.)
   • Keep exterior garbage (and kitchen compost) in tightly sealed containers
   • Handle pesticides and other products containing chemicals outside the house and apply only in recommended quantities
   • When using any strong cleaning products, or painting, keep windows open or a fan going to minimize inhaling unhealthy fumes
   • Never idle the car inside the garage
   • Use plants to improve indoor air quality
Detail window sills in wet areas

**BENEFITS**

- **Energy Savings:**
- **Water Savings:**
- **Resource Conservation:**
- **Air Quality:**

**FEASIBILITY**

- **Initial Cost:** $$
- **Difficulty Level:** T

Windows near wet areas (such as in showers or near bathtubs) need to be properly detailed to avoid rot, mold, and mildew, and prevent air leakage. When installing a window in a wet area, select a window frame that is tolerant to high levels of moisture. Use a sill that is impermeable to water and seal as if it were an outdoor sill. Use moisture-resistant or impermeable materials such as marble or other durable material. This helps conserve resources by improving the durability of window frames, sill, and sheetrock and saving long-term costs for replacements.

Seal and flash windows/skylights

**BENEFITS**

- **Energy Savings:**
- **Water Savings:**
- **Resource Conservation:**
- **Air Quality:**

**FEASIBILITY**

- **Initial Cost:** $$$
- **Difficulty Level:** TTT

Air and water leakage problems commonly found around windows and skylights can cause structural damage and indoor air quality problems. According to the Partnership for Advancing Housing Technology (PATH), most leakage problems stem from improper or insufficient flashing details or the absence of flashing. By properly sealing and flashing around windows, doors and skylights one can reduce heat loss resulting in lower energy bills and prevent water damage which could lead to costly replacement of drywall and framing.

Upgrade or replace existing windows

- **Initial Cost:** $$$
- **Difficulty Level:** T

Determining whether the home’s windows need to be updated or replaced starts with a **Home Performance Audit** (see strategy IDP2/EA51-54), which will reveal window leaks. Visual inspection may also reveal window problems. Are any of the windows cracked? Do they open to allow fresh air to enter? Are there any windows without storm windows?

Upgrade or replace single-pane with double-pane windows with low-E or spectrally-selective glass to save 10 to 25 percent per year on heating. To help offset the up-front cost, check for incentives from federal tax credits and through state and local utilities. If window replacement is not in the budget and old single-pane windows are in good condition, install storm windows in the winter months. Upgrading the sash alone can also save money. Storm windows can reduce heat loss through the windows by 25 percent to 50 percent. Storm windows also protect against impacts from rain, ice and snow. Bear in mind that good windows installed badly will not achieve expected savings, so see the link in the resources section for tips on “How to Hire an Expert Installer.” Finally, windows that are properly sealed and caulked prevent leakage of air in and out of the house and provide a protective barrier from water and noise. [For more information, see Weatherization and Energy: Weatherstrip doors and windows EA58.]

Tips

1. Add shrink-wrap plastic sheeting on windows that are rarely opened in the winter.
2. Install tight-fitting, insulating window shades on windows that feeldrafty after weatherizing.
3. In the winter, close curtains and shades at night; open them during the day. In the summer, close curtains on south- and west-facing windows during the day.

Incentive

By installing eligible windows and skylights, homeowners can receive a tax credit of 10 percent of the cost up to $200. Installation costs are not included. The maximum amount of homeowner credit for all improvements combined is $500 during the three-year period (2006, 2007, and 2009) of the tax credit.

Building Age

A historic wood window, properly maintained and fitted with a storm window, can be just as energy-efficient as a new window.

For more tips on green historic windows, see www.preservationnation.org/issues/sustainability/additional-resources/July2008WindowsTipSheet.pdf

Caution

Be careful of lead-based paints and enamels on older windows, trims, and sashes.
Upgrade existing exterior door

Benefits
- **Energy Savings:** 🍃
- **Resource Conservation:** 🌲
- **Air Quality:** 🌼

Feasibility
- **Initial Cost:** $%

**Description:**
An exterior door that is old, improperly installed, or not well sealed can contribute significantly to energy losses in a home. If the home has older doors or if installing a new door can be included as part of a larger home improvement project, replacing them will result in lower heating and cooling costs. Adding a storm door can be a good investment if a home’s existing door is old but still in good condition, however, adding a storm door to a newer, insulated door is not generally worth the expense since it won’t save much more energy. When selecting a door for energy efficiency, consider its energy performance rating and look for the Energy Star® and National Fenestration Rating Council Label. Check for federal tax credits and state and local incentives for qualifying doors.

Provide shading of skylights as needed

Benefits
- **Energy Savings:** 🍃
- **Resource Conservation:** N/A
- **Air Quality:** 🌼

Feasibility
- **Initial Cost:** $$$

**Description:**
Rooftop skylights, especially when facing south or west, cause significant household heat gain. Some skylights have built-in blinds mounted between the panes of glass that open and close to control heat gain. Skylights with electrochromic glazing to allow users to tint the glass with a push of a button. These are expensive, however, and while some exterior shading options are effective, they are not readily available. Translucent panel skylight systems are an alternative that provides optimal daylighting without glare that minimizes heat transfer. The best option is to install skylights only on north or east facing roofs.

Isolate attached garages

Benefits
- **Energy Savings:** 🍃
- **Resource Conservation:** N/A
- **Air Quality:** 🌼

Feasibility
- **Initial Cost:** $

**Description:**
Rooms attached to a garage often suffer from poor indoor air quality and air leakage. For health, safety and energy efficiency reasons, it is important that air and thermal barriers be complete and continuous between these two spaces. Installing an exhaust fan or vent in the garage can also help in removing fumes from cars and chemicals stored in the garage.

Use ceiling fans for natural ventilation

Benefits
- **Energy Savings:** 🍃
- **Resource Conservation:** 🌲
- **Air Quality:** 🌼

Feasibility
- **Initial Cost:** $

**Description:**
Use ceiling fans in conjunction with an air conditioning system in occupied rooms; people can tolerate higher temperatures when air is in motion. This reduces air conditioning use, saving money.
and electricity. In the summer, run ceiling fans in a counterclockwise motion. Ceiling fans can be used in the winter in a clockwise motion at low speeds to bring warm air back down into the occupied space.

Also consider a whole house fan to avoid air conditioner usage and expense. Generally a whole house fan is used at night and turned off during the day. It moves cooler nighttime air into the house through open windows and exhausts warm air through the attic.

Another way to cool the home is with transoms in window and door designs. Designing for convection directs cool air to enter the home on the lower floors (such as through the basement) and expels warm air through upstairs windows.

Strategic location of plants and landscaping can cool (and clean) the air before it enters the home. Finally, awnings and blinds provide additional passive cooling options.

Install a programmable thermostat

Programmable thermostats save energy and money by allowing homeowners to set temperatures based on occupancy and to schedule setting changes. This uses heating and cooling only when needed. Programmable thermostats are especially useful if the house is empty during the work week and only fully occupied on weekends. Pre-programming and proper use of a programmable thermostat saves energy costs by minimizing heating or cooling of an empty house. Save up to 2 percent on one’s energy bill per 8-hour period by lowering the temperature in the winter from 2-5 degrees while no one is home or when occupants are asleep.

Make sure ductwork is clean

Duct cleaning refers to the cleaning of heating and cooling system components in forced air systems, including the supply and return-air ducts, registers, grilles, diffusers, heat exchangers, heating and cooling coils, drain pans, fan motor, fan housing, and the air handling unit. While clean ducts help maintain healthy indoor air quality, unless done properly, cleaning ducts can cause more indoor air problems.

If a visual inspect reveals infestation, mold or extreme debris problems, duct cleaning may be necessary. If so, be sure the service provider cleans all components of the system to avoid any recontamination that may require more serious cleaning needs. Be sure the service provider is qualified by the National Air Duct Cleaners Association (NADCA). A certified service provider uses specialized tools to dislodge dirt and other debris in ducts and vacuums them out with a high-powered vacuum cleaner. Different types of ducts require different cleaning methods; sheet metal ducts with external insulation are the easiest to clean. A Duct Blaster Test should also be performed when cleaning ducts to gauge the tightness of the ductwork. Finally, be sure to cover duct registers and openings during renovation or remodeling.
Install effective ventilation

To maintain healthy indoor air quality requires proper ventilation in bathrooms, kitchens, garages and utility rooms. Kitchen exhaust hoods are an important fire safety requirement and generally aid in improving ventilation. In bathrooms and other moist areas ventilation is key to preventing mold and mildew. Installing a fan appropriate to the size of the bathroom can help keep moisture levels down. Increase efficiency by reducing the number of sharp turns in the ductwork. For quiet bathroom and kitchen fans, look for units that produce less than 1.5 sones while in use.

Offices and hobby rooms with large amounts of electronics also need extra air conditioning to handle extra heat created. Garages and storage rooms where hazardous materials are stored will require a higher rate of ventilation than other rooms in the house. If the entire house has a ventilation system, increase the rate in these specific rooms. If no complete ventilation system is installed, provide an exhaust fan in each room where necessary. Installing ductwork and exhaust fans can be complicated; using a licensed contractor is recommended.

Provide fresh air in ventilation system

When closing leaks and tightening a building’s envelope, mechanical ventilation becomes extremely important. Bringing fresh air into the spaces where people spend the most time in the home is important to maintain healthy indoor air quality. Relying on open windows for ventilation may not be enough during fall and spring, when pressure differences cannot properly ventilate the home. Also for those with allergy problems, open windows can cause respiratory problems and possibly complicate current health problems. Include a fresh intake on HVAC systems or install a dedicated ventilation system if necessary. Use a heat-recovery ventilator (HRV) that uses excess heat from the home to efficiently heat incoming fresh air. Installing HVAC and ventilation systems requires a licensed professional.

Vent all combustion-based equipment

Anytime combustion equipment is introduced into the home, it must be properly ventilated. Failing to properly vent combustion equipment, can introduce toxic gases into the house. This is most often caused by backdrafting, where unstable pressure in the equipment that relies on a natural draft to invert, instead forces the gases back into the building. To avoid backdrafting, choose equipment with sealed combustion or power-vented combustion. Most of the newer high-efficiency models already incorporate these features into their design. Wherever this equipment is installed, be sure to install a carbon monoxide detector to warn occupants if gas leaks into the building. Avoid unvented combustion equipment in the home because they release carbon monoxide and other toxic gases and add water vapor into the air, leading to potential mold and mildew problems.
### Install automatic shut-off bathroom fans

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>WATER SAVINGS:</th>
<th>ENERGY SAVINGS:</th>
<th>RESOURCE CONSERVATION:</th>
<th>AIR QUALITY:</th>
<th>DIFFICULTY LEVEL:</th>
</tr>
</thead>
<tbody>
<tr>
<td>FEASIBILITY</td>
<td>INITIAL COST: $</td>
<td>FEASIBILITY</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When installing a bathroom fan, find one that is quiet and of the appropriate size for the space. Installing a timer on a bathroom fan helps reduce energy consumption and improves indoor air quality. After showering, moist warm air in the bathroom contributes to mold and mildew growth. Installing an automatic timer vents the room and saves energy. Some bathroom fans come with a moisture sensor and turn off automatically once the room has been properly vented. Look for Energy Star® certified fans.

In general, exhaust fans should stay on for one hour after a bath or shower to effectively remove excess moisture from the room. A fan equipped with a timer ensures the fan remains on long enough to exhaust moisture completely. An electronic timer is quieter than a mechanical timer and offers a wide range of settings. Choose a timer setting with easy-to-understand instructions and be certain the timer itself is easy to operate. A delayed fan shut-off will keep the fan running for at least one hour after the homeowner leaves the room. Another option includes a motion sensor that activates the fan when anyone enters the bathroom.

### Provide daylighting

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>WATER SAVINGS: N/A</th>
<th>ENERGY SAVINGS:</th>
<th>RESOURCE CONSERVATION:</th>
<th>AIR QUALITY:</th>
</tr>
</thead>
<tbody>
<tr>

<td>INITIAL COST: $</td>
<td>FEASIBILITY</td>
<td>DIFFICULTY LEVEL: TT</td>
<td></td>
</tr>
</tbody>
</table>

Sunlight is a natural way to reduce energy use during the daytime hours. Homes that only require artificial lighting at night and on darker days save more electricity and are more aesthetically pleasing than ones that do not.

Windows and skylights are obvious sources of daylight, but balance daylight access with appropriate glazing and shading techniques. Poorly designed window or skylight layouts can increase summer cooling loads significantly. Awnings, louvers, and shutters can block direct sunlight and allow indirect sunlight into the building. Conversely, a well-designed scheme reduces heating loads significantly in the colder months. In the northern hemisphere, south-facing windows receive the most sunlight over the course of the day. For these windows, properly sized overhangs will shade the window from direct summer heat but will allow the lower winter sunlight to filter through.

An alternative to window skylights is solar tubes. The flexible cylinders of the solar tubes draw sunlight from the roof into a ceiling fixture resembling a standard lighting fixture. They are useful in smaller interior rooms without space for a traditional skylight, such as a bathroom. Translucent panel skylight systems are another means of allowing in sunlight without producing glare and minimizing heat transfer.

### Provide appropriate lighting

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>WATER SAVINGS: N/A</th>
<th>ENERGY SAVINGS:</th>
<th>RESOURCE CONSERVATION:</th>
<th>AIR QUALITY:</th>
</tr>
</thead>
<tbody>
<tr>
<td>FEASIBILITY</td>
<td>INITIAL COST: $$$</td>
<td>FEASIBILITY</td>
<td>DIFFICULTY LEVEL: TT</td>
<td></td>
</tr>
</tbody>
</table>

Lighting consumes almost 15 percent of a household’s electricity use. Provide an appropriate mix of color-correct ambient and task lighting to improve both the quality and quantity of lighting used in the home.
Two ways of determining which lighting is appropriate for a particular use are its color temperature and its Color Rendering Index (CRI).

**Color temperature** defines the color and warmness or coolness of a light source. Color temperature is measured in degrees Kelvin (K). High Kelvin temperatures (3600–5500 K) are considered “cool” and low color temperatures (2700–3000 K) are considered “warm.” Task lighting calls for cool light that produces a higher contrast than warm light and is better for visual tasks. Warm light is recommended for living spaces. A color temperature of 2700–3600 K is generally recommended for most indoor general and task lighting applications.

The **Color Rendering Index (CRI)** is a 1-100 scale that measures how colors appear under different light sources. A light source with a CRI of 80 or higher is considered acceptable for most indoor residential applications.

**Install energy-efficient lighting** [EA85]

Traditional incandescent bulbs will be phased out by 2012. The technological improvements in compact fluorescent lighting (CFLs) over the past decade have made for a smooth transition. CFLs are inexpensive, last ten times as long as traditional bulbs, and use a fraction of the electricity. They also fit into standard light fixtures, allowing for their widespread use with minimal up-front cost.

Light-emitting diodes (LEDs), currently used in a variety of applications, potentially could find their way into more traditional lighting applications. Highly efficient, durable, and non-toxic, LEDs currently cost too much to warrant their widespread use. However, rapid advances in LED technology continue to push LED lighting to more practical uses.

Wherever possible, replace incandescent bulbs with greener alternatives. It is a simple and affordable way to significantly reduce home energy use.

**Provide controllable interior shading** [IEQ187]

Rooms used frequently should have shades to reduce heat gain and minimize glare from natural light. Venetian or vertical blinds are effective, easy to install, and efficient means to control light entering the building. Manual and motorized screen shades are another means of interior shading. Accordion-shaped blinds effectively create an added layer of air preventing further heat loss. Window quilts can be used at night to prevent warm air from escaping.

**Install eco-friendly interior sheathing** [MR126]

Paper-faced drywall is the most common and least expensive finishing for interior walls. It is easy to work with and its paper composition is typically recycled from 100 percent post-consumer waste. However, paper-faced drywall is highly susceptible to moisture damage and mold growth; do not use it in moist areas of the home.
Fiberglass-faced drywall is a paperless gypsum panel often used for exterior sheathing and interior walls in mold-prone areas. It contains no cellulose, which supports mold growth. Fiberglass-faced drywall, however, cannot be recycled and because of the fiberglass it cannot be ground for use as a soil amendment.

**Select eco-friendly interior doors [MR127]**

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS: N/A</td>
<td>RESOURCE CONSERVATION: N/A</td>
</tr>
<tr>
<td>WATER SAVINGS: N/A</td>
<td>AIR QUALITY: ★★★</td>
</tr>
<tr>
<td>INITIAL COST: $</td>
<td>DIFFICULTY LEVEL:</td>
</tr>
</tbody>
</table>

Look for recycled interior doors from salvage yards or reuse vendors or choose new doors that are formaldehyde-free or have urea-formaldehyde-free wood components. Doors that are FSC-certified ensure the wood was sustainably harvested. Using recycled products or sustainably harvested wood saves virgin materials from extraction and helps the environment.

**Choose eco-friendly paints, sheens, and finishes [IEQ185/MR130/131]**

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS: N/A</td>
<td>RESOURCE CONSERVATION: N/A</td>
</tr>
<tr>
<td>WATER SAVINGS: N/A</td>
<td>AIR QUALITY: ★★★</td>
</tr>
<tr>
<td>INITIAL COST: $</td>
<td>DIFFICULTY LEVEL:</td>
</tr>
</tbody>
</table>

Traditional paints, finishes and coatings contain a variety of hazardous chemicals including volatile organic compounds (VOCs) which can be harmful to human health. Choosing zero- or low-VOC paints significantly improves indoor air quality. These products are readily available and come in a wide variety of colors and finishes. Also, choosing appropriate sheens can improve the durability of wall and other finished surfaces. For places that will be washed frequently use sheens with a high “scrubbability” rating.

To further reduce chemicals used in paints, manufacturers have recently introduced products made almost exclusively from plant oils and minerals. When possible, consider using natural paints, varnishes, finishes, and plasters instead of conventional petroleum-based products to help improve indoor air quality. The increasing availability of natural products has helped make them more competitively priced.

**Consider tile with recycled content [MR132]**

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS: ★</td>
<td>RESOURCE CONSERVATION: N/A</td>
</tr>
<tr>
<td>WATER SAVINGS: N/A</td>
<td>AIR QUALITY: ★★★</td>
</tr>
<tr>
<td>INITIAL COST: $$$</td>
<td>DIFFICULTY LEVEL:</td>
</tr>
</tbody>
</table>

When choosing tile and trim pieces, look for products that contain recycled content to help conserve natural resources. Utilizing waste from other products reduces the need for virgin materials. Recycled products can be made from glass and pre-consumer industrial waste.
Select eco-friendly wall coverings

When it is time to update wall covers, look for low-VOC-emitting products. Traditional wallpaper is coated with PVC and plasticizers that over time release chemicals found to interrupt the endocrine system. These impermeable plastic coatings also keep moisture in the walls which can lead to mold and mildew. Research linking the production and off-gassing to potential health effects spurred the introduction of many new low-VOC and natural fiber products. These products help reduce airborne chemicals and protect indoor air quality. They also prevent moisture retention behind walls. Natural and low-VOC products are slightly more expensive than traditional products and may need special care when installing. Follow any manufacturing guidelines that may come with the product.

Use non-paper-faced gypsum board in moist areas

Minimize mold growth and maintain high indoor air quality and durability by using better wall and ceiling finishes. Gypsum board (drywall) is a universally used building product in the U.S. available in several varieties that resist mold growth. The most reliable is non-paper-faced gypsum board. Paper components absorb moisture because paper is a food source for mold. Non-paper-faced gypsum, originally developed for exterior sheathing, is useful in moist areas such as basements and bathrooms.

In damp areas, cement board, mortar, or non-paper faced gypsum can be used safely. Paper-faced gypsum board should never be used as backer for tub or shower surrounds where ceramic tile, marble, or any material with joints or grout lines is used as the finish. While more expensive to purchase than conventional paper-faced products, there are long-term savings in preventing damage from mold growth. Mold resistant paper faced board should not be used in damp areas. It is important to seek comparable data to assess performance of other mold resistant claims by manufacturers, as little independent analysis is available.

Use low-VOC construction products

Like paints and coating products, construction adhesives, grout, caulking, and sealants can have high VOC content. Low-VOC products are becoming readily available and are just as durable as conventional products. Avoiding products with VOCs improves indoor air quality.
Avoid carpeting in moist areas [IEQ179]

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS: N/A</td>
<td>WATER SAVINGS: N/A</td>
</tr>
<tr>
<td>RESOURCE CONSERVATION:</td>
<td>AIR QUALITY:</td>
</tr>
<tr>
<td>INITIAL COST:</td>
<td>DIFFICULTY LEVEL: T</td>
</tr>
</tbody>
</table>

Carpeting may provide comfort, but it produces airborne dust and releases particulates from both the carpet and the padding. Avoid carpet in moist rooms or “high-spill areas” to maintain healthy indoor air quality. Carpets are difficult to clean, take time to dry properly, and can retain dust and dirt tracked in from the outdoors. Older carpet padding can deteriorate over time and may release flame retardant chemicals into the air.

Reuse existing flooring and subflooring [MR133]

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS: N/A</td>
<td>WATER SAVINGS: N/A</td>
</tr>
<tr>
<td>RESOURCE CONSERVATION:</td>
<td>AIR QUALITY:</td>
</tr>
<tr>
<td>INITIAL COST:</td>
<td>DIFFICULTY LEVEL: T</td>
</tr>
</tbody>
</table>

A great way to reduce the use of natural resources is to reuse old flooring. Often homes are made with structurally sound hardwoods or concrete. Refinishing these existing floors reduces the need to harvest new materials and reduces exposure to chemical off-gassing from new products. There are many new low- or no-VOC products for refinishing flooring.

Choose hard, low-formaldehyde floors [IEQ180/MR134]

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS: N/A</td>
<td>WATER SAVINGS: N/A</td>
</tr>
<tr>
<td>RESOURCE CONSERVATION:</td>
<td>AIR QUALITY:</td>
</tr>
<tr>
<td>INITIAL COST:</td>
<td>DIFFICULTY LEVEL: T</td>
</tr>
</tbody>
</table>

Hard surface and low-formaldehyde flooring improves indoor air quality significantly. Hard surface floors do not hold dust and particles making them easier to keep clean. Also, by using materials such as concrete, a homeowner reduces the amount of natural resources used for flooring. If choosing to use new wood, look for FSC-certified wood to ensure sustainable harvesting practices. Many floor tile now use recycled materials. Always use low- or no-VOC adhesives, grout, and sealants when installing flooring.

Use reclaimed or renewable materials [MR135-136]

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS:</td>
<td>WATER SAVINGS: N/A</td>
</tr>
<tr>
<td>RESOURCE CONSERVATION:</td>
<td>AIR QUALITY:</td>
</tr>
<tr>
<td>INITIAL COST:</td>
<td>DIFFICULTY LEVEL: T</td>
</tr>
</tbody>
</table>

Choose wood flooring responsibly to preserve natural resources. Reclaimed or rapidly renewable materials (like bamboo, cork or linoleum) significantly reduce the pressure on natural forests. If a homeowner decides to buy new wood flooring, choose FSC-certified wood to ensure the manufacturers followed sustainable harvesting practices. Other products made from cork, wheat, and recycled waste paper offer environmentally benign options. As with other finishing products, always look for low-formaldehyde and low-VOC floor finishing products to maintain a healthy indoor environment.
Refinish floors with eco-friendly products

When remodeling, reusing old wood flooring both conserves resources and preserves the character that older hardwoods gather over time. However, when looking to refinish these floors, be advised that older floors may have lead-based paint on them and should be tested. When selecting finishes, look for zero- or low-VOC finishes or a finish derived from a natural product like plant oils (i.e., linseed) or beeswax. This helps maintain the home’s indoor air quality. Some products may be hard to find so allow time to special order. Whenever possible, avoid products with heavy metals or harsh solvents. If a container has any “danger” or “warning” symbols, try and choose a different less toxic alternative. Beware of “organic” labels with finishes. Organic food is a good thing, but in terms of finishes, ‘organic’ could mean they are created from petrochemicals and probably contain solvents. Always have a constant flow of fresh air in areas when applying a finish and wear a mask for added protection. Overall, zero- or low-VOC products may cost more initially, but they pay off through reduced health concerns.

Select eco-friendly carpeting

Wall-to-wall carpeting and large-area carpets can affect air quality in the home. The carpets and pads are difficult to clean and dry properly (creating an environment for mold and mildew) and hold on to dust and other particles. Small area rugs that accent hard floors are easier to remove and clean. Furthermore, new carpets and rugs may contain VOCs that off-gas and are unhealthy to breathe. To reduce environmental and health impacts, look for carpets made from natural fibers with little or no chemical treatment. Also, purchase carpets with natural-fiber backing attached with less-toxic adhesives. Recommendations include organic cotton, hemp, sisal, seagrass, jute, or wool. Buying carpet “tiles” instead of a broadloom piece, as individual tiles can be replaced easily. Finding carpet made with low-VOC adhesives that meets Carpet and Rug Institute indoor-air quality standards. Use tacks instead of adhesive and look for recycled content or reclaimed carpet.

Install water-saving fixtures

Kitchens and bathrooms continue to be a source of significant daily water waste. Replacing existing toilets, faucets, and showerheads can reduce home water and save money. It takes energy to deliver, heat and treat water, so by using less water a homeowner decreases energy use in the home. By installing a WaterSense Labeled High Efficiency Toilet that uses 1.28 gallons or less per flush, a homeowner can save a large amount of water and significantly reduce a home’s water utility bill. Dual flush toilets have two buttons, a light flush that uses 0.9 gallons of water and a heavy flush that uses 1.6 gallons of water. When looking to replace faucets, look for fixtures that have a flow rate of 2.0 to 1.5. For replacing showerheads look for showerheads that uses less than 2.5 gpm.
Install water filtration system [IEQ175-176]  

**BENEFITS**

**ENERGY SAVINGS:**  

**WATER SAVINGS:**  

**INITIAL COST:**  

**RESOURCES CONSERVATION:**  

**AIR QUALITY:**  

**FEASIBILITY**

**DIFFICULTY LEVEL:** TT

Home water filtration systems can remove some contaminants from water and improve taste. This is an inexpensive alternative to bottled water. There are several different systems available for under the sink filtration, which include reverse osmosis, ultraviolet treatment, and (most common and least expensive) are the carbon or specialized media filters. Also it is recommended to install filters on showerheads to remove chlorine from the water for bathing.

Include a plumbing access panel [MR123]  

**BENEFITS**

**ENERGY SAVINGS:** N/A  

**WATER SAVINGS:**  

**INITIAL COST:**  

**RESOURCES CONSERVATION:**  

**AIR QUALITY:** N/A  

**FEASIBILITY**

**DIFFICULTY LEVEL:** TT

When putting in new piping, install an access panel for easy access to make repairs or upgrades. This allows for easy inspection and reduces the amount of materials to be removed and discarded in order to make an otherwise simple repair. Install the access panel at a location that is most convenient to areas that could need maintenance, like pipes going toward a shower or bath. Proper sealing of the panel avoids spaces where air and moisture can leak into the house.

Choose a high-efficiency water heater [EA79]  

**BENEFITS**

**ENERGY SAVINGS:**  

**WATER SAVINGS:**  

**INITIAL COST:** $$$  

**RESOURCES CONSERVATION:** N/A  

**AIR QUALITY:** N/A  

**FEASIBILITY**

**DIFFICULTY LEVEL:** TT

Hot water heaters are one of the biggest energy consumers in the house (between 14-25 percent of total energy usage). By replacing or upgrading an existing hot water heater, a homeowner can reduce significantly the amount of energy consumed on a yearly basis. Electric hot water heaters are not recommended for home use because of high energy demand. Gas-fired heaters with an electric ignition are more efficient than those that use a pilot light. The efficiency of a hot water heater is also determined by the efficiency of the heat exchangers, the insulation value of the tank, and the configuration of the burner. Tankless water heaters are becoming increasingly popular. These systems heat water when it is needed and eliminate the wasted energy during the storage of the hot water. However, tankless systems are not for every household. If the house uses hot water frequently in short amounts (like washing hands a dozen times a day) than the system will never reach its peak efficiency and could be wasting energy. Evaluate the home's needs and speak to a professional before buying one of these systems. When looking at gas-fired systems, be sure to choose a closed combustion system to avoid releasing toxic fumes into the house. Also, always be sure that the area around is properly ventilated.

Tips [EA79]

For efficient water heaters New Jersey BPU offers a $25 rebate:  
www.njcleanenergy.com/residential/programs/warmadvantage/warmadvantage  

Incentive [EA79]

For efficient water heaters homeowners can receive up to a $300 tax credit:  
www.pseg.com/customer/home/install/waterheaters.jsp
Consider eco-friendly piping material

There are several common household piping options: cast iron, copper, chlorinated polyvinyl chloride (CPVC), PEX (cross-linked polyethylene), vitrified clay, and HDPE (High Density Polyethylene). Heavy cast iron pipes are energy intensive to mine and manufacture, and can corrode over time. They are, however, good in situations with large temperature fluctuations. Mining ore for copper pipes damages the environment and the manufacture of the pipes are energy intensive. There is some recycled content in newer copper piping, but most is still virgin material. Copper piping has high heat conductivity, so they need insulation to be efficient. PEX pipes are composed of a plastic made from carbon and hydrogen so environmentally-speaking it is relatively clean. Vitrified clay pipes have the lowest thermal expansion and therefore are good in places with high temperature fluctuations. They are very durable and resist corrosion from chemical reactions, however, like iron, they are very heavy. Variety in the sizes for new piping systems maximize efficiency by better matching the size to the use. Copper pipes may need insulation, but PEX, since it can be matched to specific use, is more efficient and may not need any insulation. CPVC pipe is not recommended, for although it does not need much insulation and is very inexpensive, the environmental costs of production are very high.

Reconfigure plumbing for efficiency

Advancements in piping materials and plumbing systems cut installation and material costs, conserve water, and save energy. Cross-linked polyethylene (PEX) piping material has quickly earned a reputation as a durable replacement for copper because it is:

- Flexible – allowing for fewer joints and an easier (and quicker) installation
- Durable - capable of withstanding extreme temperatures and highly resistant to chemicals
- Consumer friendly – quieter than traditional piping materials and offered in color-coded PEX tubing for simple identification of cold and hot water lines
- Energy-efficient – reduces heat loss from water in the pipe because it is a better thermal insulator than copper
- Water efficient – right-sizing capability allows for quicker hot water delivery

PEX also lends itself to home run or parallel pipe configurations in which hot and cold pipes originate at a manifold and service individual fixtures with dedicated supply lines. Home-Run systems can be installed more quickly (because of flexible piping) than more rigid and conventional “tree” type plumbing systems. The dedicated supply lines from the manifold to the fixture – particularly in the hot water supply lines – are often smaller in diameter for a home-run system, so less water goes down the drain while waiting for hot water at the fixture. Finally, home-run systems operate much like an electrical system breaker box, allowing homeowners to easily turn off the water for repairs or maintenance.
Install instantaneous hot water heater

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS:</td>
<td></td>

<td></td>
</tr>
<tr>
<td>DIFFICULTY LEVEL: TT</td>
<td></td>
</tr>
</tbody>
</table>

Installing an instantaneous or on-demand hot water heater greatly increases efficiency by eliminating the wasted heat during the storage of hot water. These devices save 8-14 percent compared to a conventional heater with a tank. When looking to install one of these hot water heaters, evaluate the home's water use first. If hot water use in the home is high, then this will not be the right system. If hot water use is relatively centralized, these systems can save on energy, materials for piping, and water wasted in the heating process. For these systems to run properly, they should be used with highly efficient fixtures. They do not provide the high flow rate of tank systems and provide lower water pressure than traditional tank systems. Use a professional to install these systems as they require specialized knowledge and some homes may not be equipped to meet the high voltage demanded by the electric version of these systems.

Select a high-efficiency clothes washer

Clothes washers are responsible for about 22 percent of household water consumption or about 13,000 gallons of water each year. Today's energy-efficient washers reduce water use and energy bills. Replace a clothes washer when 1) a repair will cost more than half the price of a comparably equipped new appliance, and 2) a washer is more than seven years old. If you are in the market for a new clothes washer consider the following:

- In selecting a washer load capacity, consider the household's largest routine load – larger capacity means fewer loads, saving time and energy
- Front-loaders use less energy and water, are usually gentler on clothes, and have faster spin speeds that drain more water out of laundry than regular top-loaders do
- Look for washers with the Energy Star® label

Front-loading washers are more expensive than top-loading washers, but in New Jersey, rebates are available for units that meet Tier 3 Energy Star® standards which require a Modified Energy Factor (MEF) of 2.2 or higher and a maximum Water Factor (WF) of 4.4. There is no certification for dryers, but a unit with a moisture sensor turns off automatically when clothes are dry saves money and energy.

Select an energy-efficient refrigerator

<table>

<td></td>
</tr>
<tr>
<td>DIFFICULTY LEVEL: T</td>
<td></td>
</tr>
</tbody>
</table>

Refrigerators consume more electricity than any major kitchen appliance. Energy efficient refrigerators like Energy Star® models are about 40 percent more efficient than refrigerators built before 2001, and 50 percent more efficient than those built before 1993. If an existing refrigerator is more than 10 years old, consider upgrading to a refrigerator that meets or exceed Energy Star® standards as a new refrigerator with an Energy Star® label uses at least 20 percent less energy than one required by current federal standards.

Tips

By using the cold-water option on a washer, one can save on energy bills by eliminating the energy needed to heat the water. Season and weather permitting, hang clothes to dry; most of the energy consumed by a single load of laundry is from drying, so by using the sun and fresh air one can reduce their energy consumption.

Incentive

Check the New Jersey's Clean Energy Program for rebates on eligible Energy Star® qualified clothes washers.

Tips

Cleaning the refrigerator coils once or twice a year can help to improve an existing refrigerator’s efficiency. Keep some distance around the refrigerator to allow for proper air flow around the coils.
Size, options and freezer compartment configurations affect energy use. A larger unit may be Energy Star® certified, but a smaller unit may still use less energy, so choose the smallest refrigerator that appropriately meets household needs. Features (such as water dispensers) use energy, so fewer features mean both greater energy efficiency and a lower likelihood of repairs. Top freezer models are generally more energy efficient than side-by-side models. Leave room around the unit for proper air flow around the cooling coils to ensure peak efficiency. Maintaining the unit is also important.

Choose an energy-efficient dishwasher

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS:</td>
<td>WATER SAVINGS:</td>
</tr>
<tr>
<td>RESOURCE CONSERVATION:</td>
<td>AIR QUALITY:</td>
</tr>
<tr>

<td>DIFFICULTY LEVEL: ↑</td>
</tr>
</tbody>
</table>

Most dishwasher energy use goes toward heating water, however, today’s high-efficiency dishwashers use as little as three gallons of water thanks to sensors, high-efficiency pumps, and improved filtration. The expected life of a dishwasher is 9-12 years, and the payback period for a new dishwasher is long, but studies suggest it is more sensible to replace a dishwasher that is more than six years old rather than pay for repairs. Look for dishwashers the carry the Energy Star® label, which are over 40 percent more energy-efficient than the minimum government standards.

Install energy-efficient cooking appliances

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS:</td>
<td>WATER SAVINGS:</td>
</tr>
<tr>
<td>RESOURCE CONSERVATION:</td>

<td>DIFFICULTY LEVEL: ↑</td>
</tr>
</tbody>
</table>

Cooking itself does not contribute significantly to overall home energy use, but preheating does, making it sensible to invest in an energy-efficient model. When shopping for new cooking appliances or remodeling the kitchen, consider making a fuel switch since running gas pipes, vents, and electrical connections will influence the layout of the kitchen. Consider cooking preferences and local gas and electric rates. If another appliance such as a furnace, clothes dryer, or water heater is also on a switch list, take this into consideration when you look at placement and installation costs.

In general, electric ranges and ovens are more efficient than gas units. The most efficient ovens are convection ovens that cook by circulating hot air around the food, using only one-third as much energy to operate as conventional ovens. They produce further savings through reduced cooking times because the food is more evenly exposed to heat. Among electric ranges, induction models may cost more but they are also the most efficient.

In terms of gas units, look for electronic or thermal igniters instead of standing pilot lights. For smaller meals, consider using a microwave oven or a toaster oven that require less energy than a large oven. Self-cleaning gas or electric ovens are more efficient because they have more insulation than non-self cleaning models.

Select energy-efficient office equipment

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>

</tr>
</tbody>
</table>

Today there are about 18 million home-based business owners and 24 million telecommuters. Working from home eliminates commute times and transportation related emissions, but it contributes to higher electricity bills to power office equipment and lighting. In fact, small electronic
devices alone account for 16 percent of an average home’s energy bill. Office equipment that has earned the Energy Star® label uses less energy to perform regular tasks and automatically enter a low-power mode when not in use, thereby reducing phantom loads. Up to 75 percent of the electricity these units consume occurs while these devices are turned off. When buying new office equipment, consider both the standby and the operating power consumption.

Energy Star® ratings are available for computers, monitors, printers, scanners, copiers, fax machines, multi-function devices (machines that combine printing, scanning, and faxing), lighting, cordless phones, answering machines, audio equipment, and room air conditioners.

**Install single-throw shut-off valve [MR124]**

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS: N/A</td>
<td>INITIAL COST: $</td>

<td>DIFFICULTY LEVEL: TT</td>
</tr>
<tr>
<td>RESOURCE CONSERVATION:</td>
<td></td>
</tr>
<tr>
<td>AIR QUALITY:</td>
<td></td>
</tr>
</tbody>
</table>

A single throw shut-off valve is a quick inexpensive device to help prevent leakage problems. Installing this simple valve on the supply line for the hot and cold water efficiently allows the user to shut off a malfunctioning system before it leaks substantial amounts of water.

**Install drain pan for clothes washer [MR125]**

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS: N/A</td>
<td>INITIAL COST: $</td>
</tr>
<tr>
<td>WATER SAVINGS:</td>
<td>DIFFICULTY LEVEL: TT</td>
</tr>
<tr>
<td>RESOURCE CONSERVATION:</td>
<td></td>
</tr>
<tr>
<td>AIR QUALITY:</td>
<td></td>
</tr>
</tbody>
</table>

More and more homeowners today install laundry rooms over finished spaces instead of in basements and utility rooms. Because of this trend, it is important to install a drain and drain pan below the clothes washer to avoid the damage that could be caused by a burst or a leak in the equipment. This will conserve resources and avoid potentially costly repairs.

**Provide air-lock dryer vent [EA72]**

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS:</td>
<td>INITIAL COST: $$$</td>
</tr>
<tr>
<td>WATER SAVINGS: N/A</td>
<td>DIFFICULTY LEVEL: TTT</td>
</tr>
<tr>
<td>RESOURCE CONSERVATION:</td>
<td></td>
</tr>
<tr>
<td>AIR QUALITY:</td>
<td></td>
</tr>
</tbody>
</table>

Vents for the dryer that expel hot moist air to the exterior can be a significant source of leakage. Install a vent cap to help reduce both air leakage to the exterior and the overall heating load in the home.

**Minimize dryer duct length and turns [EA73]**

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>FEASIBILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENERGY SAVINGS:</td>
<td>INITIAL COST: $</td>
</tr>
<tr>
<td>WATER SAVINGS: N/A</td>
<td>DIFFICULTY LEVEL: TT</td>
</tr>
<tr>
<td>RESOURCE CONSERVATION: N/A</td>
<td></td>
</tr>
<tr>
<td>AIR QUALITY:</td>
<td></td>
</tr>
</tbody>
</table>

A dryer vents properly when it has the right resistance to air flow in the ductwork. Minimizing the length and number of turns in the duct improves the capacity of the dryer to run efficiently. If needed, install a booster exhaust fan, following the manufacturer’s guidelines for the maximum turns and length to retain efficiencies from the improvement.
Select eco-friendly furniture

Before purchasing new furniture, consider refurbishing or using existing furniture in new ways, or buying salvaged items. When purchasing new furniture, select products from companies with responsible business practices that use recycled materials, FSC-certified wood, formaldehyde-free, and low-VOC finishes. Also, spending a little more up front to purchase high quality, solid furniture and cabinetry will help prevent the premature replacement and maintenance of the home and will use fewer resources in the long run.

Look for furnishings made locally. Products produced outside the United States and Canada use more transportation resources traveling to New Jersey. These imports also tend to have fewer controls on formaldehyde and VOC content.

Choose moisture-resistant furniture for longer life to save money and preserve natural resources. Select products made from certified sustainable wood, reclaimed materials, bamboo, recycled or recyclable metal or plastic, fixable materials, and durable materials for further value.

Select eco-friendly cabinetry and countertops

When choosing materials for cabinets and countertops, consider salvaged items first. Refinishing old cabinets or furnishing countertops from salvaged stone or recycled material greatly reduces the energy intensity needed to process virgin materials.

If purchasing new cabinets, look for retailers that utilize recycled materials, FSC-certified wood, formaldehyde-free materials, and low-VOC finishes. In 2006, the Kitchen Cabinet Manufacturer's Association created a voluntary rating program called the Environmental Stewardship Program (ESP). ESP-certified cabinets are a good sustainable option. Conventional cabinetry contains urea formaldehyde that off-gasses at room temperature and can pose long-term health risks. Also consider wood veneer cabinets which give the look and feel of solid wood but use a fraction of the resources.

For countertops, there are several alternative materials that are more environmentally-friendly than conventional laminate or granite countertops. These include recycled concrete, glass tiles, plastic, paper composite, terrazzo, and wood. Locally recycled or produced items are preferable, especially to imported furnishings from countries where standards on VOCs, formaldehyde and other toxic content may be more relaxed.

An investment in more durable high-quality materials, while more expensive initially, serves a dual purpose; not only will it benefit the environment and enhance the quality of the indoor environment, it will also save money and future resources by reducing the need for replacement of these items.
Support local craftsmen  [MR153]

An easy way to promote sustainability is to buy art, furniture, and other home accessories from local artists and artisans. Usually local artists and indigenous peoples are more protective over the ecosystem. It is also possible to converse about the materials used in the production of their art if there are any particular concerns about their sources. Though almost any green product is available on the internet, a superior choice is to buy green products and services made and sold as close to home as possible. By doing so one uses products more appropriate to the local region and helps build a strong local economy.

Select furniture that is easy to clean  [IEQ192]

When looking for furniture and other items for the home, consider how easy they will be to clean and maintain. Items with reduced maintenance and cleaning needs are replaced less often, mitigating any higher up-front expenses by reducing future costs. Replacing furniture and household items less often conserves resources, reduces the need for new production, and eases the burden on landfills. Materials that are easier to clean require fewer chemical products to be used within the home as well. Products that can be cleaned with natural “green” cleaning agents will also help maintain healthy indoor air quality.

Select healthier window treatments  [IEQ193]

Most people do not think about window treatments as a way to go green, but consciously selecting these elements can have positive impacts. Good window treatments reduce harmful UV radiation and increases passive heating in the winter while keeping out excess heat in the summer and generally reducing heat loss. However, some drapes are very porous, thus absorbing dust and airborne particles. The difficulty in removing dust or cleaning the drapes can degrade air quality inside the home. Also, avoid curtains treated with toxic flame-retardants which are unhealthy to inhale. If possible, choose non-porous treatments like blinds and shutters and be careful to look for products with zero- or low-VOC finishes.
### Use green cleaning products/strategies [IEQ196]

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>ENERGY SAVINGS:</th>
<th>WATER SAVINGS:</th>
<th>INITIAL COST:</th>
<th>FEASIBILITY</th>
<th>DIFFICULTY LEVEL:</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESOURCE CONSERVATION:</td>
<td>🌳</td>
<td>🌳</td>
<td>$</td>
<td>🍃</td>
<td>🍃</td>
</tr>
</tbody>
</table>

Using environmentally conscious cleaning products is healthier for indoor air quality and for occupants. Given the frequent use and close exposure to the user, toxic VOC-releasing cleaning products are dangerous to be around and inhale. Using less toxic cleaning products also keeps rivers cleaner because when products do end up down the drain, they do less damage to the ecosystem. This is especially true for laundry and dishwashing detergent and bathroom cleaning products, which flow directly down the drain.

### Regularly maintain equipment [EA91]

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>ENERGY SAVINGS:</th>
<th>WATER SAVINGS:</th>
<th>INITIAL COST:</th>
<th>FEASIBILITY</th>
<th>DIFFICULTY LEVEL:</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESOURCE CONSERVATION:</td>
<td>🌳</td>
<td>🌳</td>
<td>$</td>
<td>🍃</td>
<td>🍃</td>
</tr>
</tbody>
</table>

Regular maintenance of appliances and mechanical equipment in the home greatly reduces home energy demand and the amount of repairs and replacements that will need to be made on the equipment. Simple things, like vacuuming refrigerator coils, emptying the lint trap before every load in the dryer, cleaning oven trays, and emptying the dishwasher food scrap bin can help to keep equipment running efficiently and save money. Follow manufacturers’ guidelines for maintaining various appliances.

### Designate a built-in recycling center

<table>
<thead>
<tr>

<td>🌳</td>
<td>🌳</td>
<td>$</td>
<td>🍃</td>
<td>🍃</td>
</tr>
</tbody>
</table>

Recycling at home reduces household garbage and landfilling of useful materials by up to 75 percent. By recycling, one can also decrease the amount of *virgin materials* extracted from the environment and reduce the overall strain on natural ecosystems. Many products containing toxic *heavy metals* and *solvents* require special arrangements for disposal. Proper disposal or recycling of these products prevents the contamination of local waterways and soils.

When buying for the home, look for products that contain the most *post-consumer recycled content* to ensure the least impact on the environment (i.e. toilet paper made from recycled paper). Many home products, especially paper products, are becoming available with *recycled content*. As part of your kitchen design, include waste disposal compartments that allow easy sorting of recyclables into the relevant types, including paper, mixed glass metal and plastics, an aluminum can crusher, and even compost and hazardous waste. By incorporating recycling into a kitchen design, it’s easy for homeowners to properly recycle waste.

Location of Project: Montclair, New Jersey

Interior Designer: Jacqueline Germany, President-Owner, and Principal Designer, Nina’s Nuances Interior Design, Inc.

General Contractor: Jacqueline Germany

Overview and Scope

This project incorporated a total kitchen remodel with upgrades to the HVAC and water resource systems. The impetus for this green design and renovation project was twofold. The primary reason was that the kitchen did not meet the client’s needs: it was outdated, aesthetically unappealing, inflexible, and functionally inefficient. This client was very conscious of his personal use of everyday household items and overall energy and resource consumption. Therefore, when deciding to remodel and renovate, the client chose to employ energy and environmental conservation strategies.

Design Approach

The environmentally-conscious client provided the principal inspiration for the project, however, being the designer’s first truly “green” project opportunity, the designer was equally as excited about completing the remodel. The team undertook the project in 2004 at a time when resources for green design in the residential arena were more limited and the public’s knowledge of the benefits and rewards of “green design” was not as sophisticated as it is in 2009. This provided some challenges but also gave the project a more innovative feel.

Team and Process

The respective backgrounds of the homeowner and designer complemented each other well. The homeowner possessed significant experiential insight as to what green products were available at the time, while the designer, by virtue of training in the environmental sciences and interior design, brought a professional awareness and knowledge of the synthesis and composition of the products. Facilitating the implementation of the green design aspects was the eagerness of suppliers to promote their green products and services.

Finance

At the time of the project, the cost of utilizing green design techniques was roughly 27 percent higher than conventional design; however, the rapid increase in availability of green design choices and products over the past several years has diminished this premium. For the designer, this project served as a “barometer” for project-related costs. Relative to today, the remodel came well within budget, even with the extra costs for the green features. The client reported energy savings of approximately 20 percent over the first full year following the renovation, and when he decided to sell the home in 2007, the green kitchen turned out to be the most compelling factor in the new owner’s decision to purchase.

Lessons and Trade-offs

Through this project, both the client and designer learned a lot about the varying levels of “greenness” in products marketed as such. When researching green products, they found that one needs to examine carefully the product information and Material Safety Data Sheets (MSDS) to verify the accuracy of the claim. The homeowner and designer were surprised by the lack of quality in some green-labeled products. Therefore, they felt that research into product choices was critical. Luckily, there are several reliable resources available today as well as many more practicing green design and remodeling professionals.

“In our efforts to help the environment by adhering to green principles of living, we often times forget to factor in how we dispose of our waste products...An important part of our efforts to do green building, design, or remodeling should be how we deconstruct that environment and what we do with its components and waste.”

- Jacqueline Germany

Before After
List of Green Strategies

**Energy Conservation**
- Replaced original appliances with energy-efficient ones
- Replaced original lighting fixtures with energy-efficient fixtures and lamps
- Utilized dimmer switches and more effective lighting controls
- Upgraded windows to improve insulation

**Water Conservation**
- Replaced original water heater with a tank-less model that heats water on demand
- Incorporated a reverse osmosis water filter with an instant hot water faucet
- Installed a whole-house water filter with water softener

**Indoor Air Quality**
- Used low-VOCA paint and non-toxic interior finishing products on cabinets, walls, and flooring
- Replaced HVAC system and added new vents and filters
- Added a cooking hood with pollution controls to aid clean exhausting of odors and fumes
- Replaced old plaster and lath with paperless sheetrock

**Sustainable Materials**
- Installed countertops made from Azrock, a granite alternative made from 70 percent consumer recyclable materials
- Installed cabinets made from river-recovered wood
- Installed bamboo flooring
- Reused door hinges and some antique hardware from original kitchen
**Case Study**

**Location of Project:** Elkins Park, PA  
**Homeowners:** Mr. and Mrs. Ryan Quinn  
**Interior Designer:** Lori Jacobsen, Lori Jacobsen Design, LLC.  
**Area Affected:** 190 sq. ft.

---

**Overview and Scope**  
The primary objective of the design firm was to create a safe and healthy nursery for an expanding family. Working within the framework of a nearly seventy-year-old home, the team made minimally invasive architectural changes to maintain the integrity of the home. Without changing the layout of the existing space, they focused on “choosing materials and products that are healthier for people, conserve resources and energy, and are resource efficient (as defined by ASID, June 2007).” Subscribing to the parameters of sustainable design, the constraints of the existing space, a fixed budget, and consideration of time, they created an eco-friendly or “green” baby’s nursery.

**Design Approach**  
The homeowners wanted to create the safest and healthiest environment for their baby. The firm helped to educate the couple on everyday products that can have an adverse effect on their health and helped the homeowners both select safe, environmentally-friendly products and make changes to improve indoor air quality.

**Team and Process**  
Lori Jacobsen Design worked together with the homeowners throughout the design process. The project began with an in-home consultation with the clients. After defining the design needs of the client and considering the budget, they worked together to create a plan that met those needs. The homeowners were then asked to approve the final design plan.

**Finance**  
Working with a budget of $10,000 the team was pleased to find out that their green choices and strategies came in under budget.

---

**Lessons and Trade-offs**  
Because of their extensive knowledge and continuing research in the area of green design, the design firm was not surprised by the project cost. To create a non-toxic nursery, the firm made suggestions to the homeowner about removing materials that could degrade indoor air quality. In general, the firm advises homeowners to participate in the design process, which helps create a transparent plan with few or no surprises in the end.

“This particular project was a dream. The client’s and our firm’s green objectives were completely aligned. Therefore, we all were on the same page from the beginning to the end.”  
- Lori Jacobsen
List of Green Strategies

Energy Conservation
• Checked heating and cooling systems to ensure optimal efficiency
• Upgraded air filters
• Installed energy-saving window shades and insulators

Resource Conservation
• Installed area rug made from 100 post-consumer recycled content (polyethylene terephthalate (PET) from recycled plastic bottles)
• Repurposed a salvaged chair using remnant fabric from a furniture manufacturer

Indoor Air Quality
• Removed all existing materials with high-VOC contents
• Used low-VOC paint
• Refinished hardwood floors with a no-sanding and non-toxic finishing product
• Cleaned floors with a neutral product that contains no harmful solvents
• Used environmentally-friendly, low-VOC carpeting and furnishings
• Chose a natural organic wool fiber and cotton mattress and bumpers for the crib

Repurposed chair from remnant fabric
Location of Project: Highland Park, New Jersey
Homeowners: Randall Solomon and Rebecca Hersh
General Contractor: Richard Stryker Contracting
Area Affected: approx. 1350 sq. ft.

Overview and Scope
This green remodel of a 90-year-old craftsman bungalow included an upgrade to a high-efficiency natural gas furnace, replacement of single-pane windows, installation of spray denim insulation, and the addition of a dual-layer high-venting roofing system. Green interior renovations included upgrades to the kitchen with Energy Star® appliances and installation of water saving fixtures and dual flush toilets in the bathroom. Existing materials were preserved whenever possible, such as exterior cedar siding, wooden porch floor boards, antique doors and fixtures, and subway-style bathroom tiles. Care was also taken to properly remove lead paint and to use only non-toxic paints and finishes.

Design Approach
Randy and Rebecca wanted to design a home that embraced their sustainable values and lifestyles, and that would save them money through reduced utility bills, and provided a healthy environment for their growing family.

Team and Process
The homeowners were the driving force behind the green aspects of this project. They researched and proposed almost all of the green techniques and materials that went into the remodel, working step-by-step with the contractor to decide on the best options. By communicating the commitment to green design from the start, the homeowners made sure that the contractor also understood the importance of reducing construction waste materials and using non-toxic finishes whenever possible.

Finance
The homeowners looked to reduce costs and conserve resources by preserving and reusing existing features of the home. For example, instead of replacing bathroom tile with all new recycled content tiles, they only replaced the most worn out sections with new tiles. When it made sense to replace older systems (such as pre-1994 water guzzling toilets) the homeowner chose to invest in greener alternatives, such as low-flow dual flush toilets, that cost more up-front but that will pay for themselves in reduced water bills over time.

Lessons and Trade-offs
Do your homework. The homeowners didn’t have to hire a “green” contractor but they did have to put in the extra time and effort to research green features and materials and to communicate these choices to the contractor.

“The good news is that the dual-flush toilets are a big hit with our friends… the bad news is that anytime we have a guests over we end up using more water because everyone wants to check them out!”
- Randy Solomon

Upstairs bathroom before
List of Green Strategies

Energy Conservation
- Replaced old single-pane windows with energy-efficient double-pane, low-E, argon filled windows with fiberglass composite frames
- Upgraded existing oil/steam heating system with highly-efficient (87 percent efficient) natural gas/hot water furnace
- Installed zone heating and programmable thermostats
- Upgraded kitchen appliances with Energy Star® dishwasher and refrigerator
- Added spray denim insulation (recycled blue jeans) to attic, basement, and exterior walls where no or little insulation existed
- Sealed cracks and leaks to reduce air infiltration
- Installed a dual layer, high-venting roofing system to reduce temperature build-up inside the attic during the summer months

Water Conservation
- Installed low-flow faucets and shower heads and added faucet aerators to existing fixtures
- Installed dual flush (0.8 and 1.6 gallon per flush) toilets

Resource Conservation
- Preserved 90 year old existing cedar siding
- Refurbished antique bathtub with a new coat of paint
- Preserved black and white subway tiles in upstairs bathroom by replacing only broken tiles
- Refinished and reused antique doors and fixtures
- Replaced rotten floor boards on the front porch with antique floor boards in the attic where they could be appreciated

Indoor Air Quality
- Professionally stripped lead paint from windows and doors
- Vacated the house during the renovation to avoid construction-related dust and air pollution
- Used low-VOC water-based finishes on all trim work
Location of Project: Chatham Township, New Jersey  
Homeowners: Ken and Kathy Abbott  
Architect: Brian and Janet Siegel, Siegel Architects  
Interior Designer: Eco-Interiors by Patricia Gaylor  
General Contractor: John Marinaccio Construction  
Green Building Consultant: Anna Hackman  
Landscape Architect: Back to Nature  
Organic landscaper: Greenpath Organic Landcare

Overview and Scope
Located in Chatham Township, New Jersey, this project entailed significant changes to a home previously renovated in 1988. It included changes to the kitchen, dining room, and family room as well as the addition of new living space over the garage. The dining room was relocated to its original location in the front of the house while the kitchen was shifted over to the dining room's position. This allowed the kitchen to become the “heart” of the home, providing a connection to the deck, family room, mudroom, and dining room. The wall between the new kitchen and existing family room was opened up completely, letting light flow from front to back of the house and giving a view of the family room and backyard from the kitchen. The mudroom, removed during the previous renovation, was restored. All of this reconstruction was done within the existing footprint of the house, except for a 72 square foot extension in the rear corner to make enough room for an office off the mudroom.

The 366.5 square foot addition above the garage contains a fifth bedroom, bath and laundry room. To make this section over the garage blend in with the rest of the house, the architect designed a hip roof for the entire house.

Design Approach
The homeowners, Ken and Kathy Abbott, were very focused on a green renovation. Their major goals included improving traffic flow and daylight downstairs, getting more counter space and cooking space in the kitchen, and providing an extra room for a new baby and an office upstairs.

Team and Process
Ken and Kathy Abbott provided the initial impetus for the green remodel. Working with the architect, the green building consultant, and the designer, she was very mindful of trying to save energy, re-purpose items she already had, use local materials, and keep the indoor air quality as clean as possible.

Finance
The Abbotts wanted to make the renovations as “green” as possible without incurring much additional expense. To that end, the only thing that cost more up front was the solar water heater, for which the estimated payback period was eight years.

Lessons and Trade-offs
If able to do it all over again, the Abbotts would choose an architect that was LEED certified, as they felt that they needed to educate the architect and builder on the green aspects of the project. One major lesson would be to perform air sealing before laying the sheetrock; they performed the air sealing after the building was done and afterwards an energy audit showed lots of air leaks from the attic and basement. One major design change would be to avoid putting recessed “can” lights (also called high-hats or recessed downlights) in ceilings that open to unconditioned spaces, such as the cathedral ceiling in the family room or upstairs rooms, because they allow unwanted heat flow between conditioned and unconditioned spaces.

“I love my bioswale, stream and organic gardens. I also like that we didn’t put as much construction waste in the landfill as we would have with a conventional demolition or carpenter. I think about what my children and their children will do as landfill space becomes scarcer and scarcer. Sustainability is important to me. I felt a responsibility not to add to my family’s carbon footprint.”

- Kathy Abbott

Solar hot water heating
List of Green Strategies

Energy Conservation
- Replaced 30-year-old windows with new low-E windows throughout the house
- Installed triple cellular blinds in master bedroom
- Installed new Energy Star® appliances
- Added two solar panels used for hot water

Water Conservation (Outdoors)
- Ensured that there would be no net increase in stormwater runoff from the slight increase in our house footprint
- Contoured the garden on both sides of the house to absorb rain water
- Built a bio-swale containing attractive native plants on the uphill side of the yard that historically collected too much rain water and caused basement flooding
- Used sump pump water to make a landscaped stream that provides a frog habitat

Indoor Air Quality
- Used zero-VOC paints
- Installed formaldehyde-free, sustainably-harvested wood kitchen cabinets
- Purchased natural jute fabric for window treatments
- Used water-based wood floor finishes

Resource Conservation
- Repurposed existing kitchen cabinets into two armoires and one laundry cabinet
- Altered existing wall unit in the family room to fit a new flat-screen TV
- Repurposed old kitchen sink into a laundry sink
- Installed recycled glass bathroom countertops and border tiles
- Installed an acrylic laundry countertop made from recycled content
- Purchased handmade kitchen tiles from New Hampshire, meeting criteria for locally-based products
- Requested a separate dumpster for concrete for the demolition of the old front porch and sidewalk

Sustainable Sites
- All the plantings, grass, etc., were planted with no pesticides
- Chose an organic landscaper to take care of the lawn and garden
Overview and Scope
This house is an 1801 Federal-style farmhouse, one of the oldest continually-occupied homes in Montclair, and is on both the New Jersey and the National Registers of Historic Places. The current owners worked to achieve a balance between preservation of the historic character and fabric with green environmental standards and the everyday needs of an active family lifestyle. The renovation focused on opening up rooms and repurposing space. This included updates to the existing kitchen, family room, laundry room, and the addition of a breakfast room.

Design Approach
Designer Patricia Gaylor and the homeowners, Jeff and Amy Plaut, both desired to do as green a renovation as possible. The designer worked with the Plauts to develop an environmentally-conscious, practical design that also preserves the historic quality.

Team and Process
Patricia worked with the Plauts on the general look and plan for the renovation, and Patricia specified all the products being used to be as green as possible. All plywood used on the renovation by the contractor contained no added formaldehyde, energy-efficient lighting and appliances were specified, and the cabinets used were no added formaldehyde plywood boxes with a low-VOC paint finish.

Finance
The cost of the renovation was considerably high to begin with due to the age of the home. Special consideration had to be taken at every turn to keep costs to a minimum. But for the most part, selections were made on the basis of their sustainability and green quality, not over high price. The construction and materials costs were fair. There will be a huge return on investment in energy savings. Before the renovation, the house was leaky, and the homeowner’s heating bills were very high. Good insulation, the addition of radiant heat flooring in the kitchen, and energy-efficient windows contribute to the new tighter building envelope.

Lessons and Trade-offs
The major surprise was how much work was required to fix old renovations and get the home up to current code. While this was expected for such an old house, the costs were higher than anticipated. Although the project was completed on time, the team ended up substantially over budget due to the poor condition of the home’s infrastructure. However, both Patricia and the Plauts were very satisfied with the results.

“I thoroughly enjoyed working on a period renovation, and melding new technologies with the old house…Green remodeling is the only way to go, as far as I’m concerned. As a designer, it’s my job to show the homeowner that a remodel of her home should be as healthy to the family as possible, leave as low a carbon footprint as possible, and make it as energy-efficient as possible. I think these things can be accomplished in a ‘green’ fashion with very little in the way of extra cash output…What surprised me the most? Nothing! Being in the remodeling business for so many years, green or not, it’s always a challenge.”

- Patricia Gaylor

Location of Project: Montclair, New Jersey
Homeowners: Jeff and Amy Plaut
Architect: John Thomas Collins
Interior Designer: Eco-Interiors by Patricia Gaylor
General Contractor: Woodhaus Construction
Area affected: 1000 square feet
**List of Green Strategies**

**Energy Conservation**
- Selected **Energy Star®** appliances, including the refrigerator, dishwasher, television, and clothes washer and dryer
- Purchased a stove and refrigerator made domestically
- Installed hydronic radiant heat under the kitchen floor
- Installed highly efficient **low-E** glass and argon filled windows
- Chose borate-treated blown-in **cellulose insulation** for the space between the interior and exterior walls for significantly increased energy efficiency
- Used **CFLs** in the majority of light fixtures, including the outside fixtures

**Water Conservation**
- Installed water filtration systems at sinks to eliminate use of bottled water
- Installed low flow faucets and faucet aerators

**Indoor Air Quality**
- Built cabinets from wood with no added **formaldehyde**, and painted them with **low-VOC** paint
- Painted interior walls with environmentally-friendly **low-VOC** paint
- Purchased laundry room cabinets made of medium-density fiberboard (MDF) with no added urea **formaldehyde**
- Coated soapstone countertops are coated with food-grade mineral oil once a month

**Sustainable Materials**
- Stripped and repaired the original brick hearth to restore it as the focus of the kitchen
- Constructed porches using local bluestone and flooring made from **recycled content**
- Installed eastern white pine floors, harvested from family-owned, responsibly-managed New Hampshire forests
- Used domestic clay for the butler’s pantry wall tile made by an environmentally responsible New Hampshire firm that reuses clay waste, water for processing, and shipping boxes
- Installed white Danby marble countertop from Vermont in baking area
- Installed Marmoleum linoleum flooring, made from **jute**, flax, and linseed oil
Location of Project: Galloway, New Jersey  
Homeowners: Stephen and Barbara Fiedler  
Interior Designer: Fiedler Designs, LLC  
General Contractor: Fiedler Designs, LLC  
Area affected: 350 sq. ft.

Overview and Scope
This project involved a total renovation of an existing kitchen and dining room into a combined kitchen with two sit-down eating spaces. The “great room” effect of this gathering space was the goal of the design, and the materials used helped meet the design goal of a total “green” or sustainable kitchen.

Design Approach
The Stephen and Barbara Fiedler looked to the U.S. Green Building Council’s Leadership in Energy and Environmental Design (LEED) for general green building guidance. They were inspired initially by the Jackie O’Neil LEED home in Perkiomenville, Pa.

Team and Process
The project involved numerous phone calls to green product suppliers and requests for product samples. The Fiedlers visited green product installation showrooms, read blogs on green products and attended seminars and conventions to educate themselves on green kitchen remodeling strategies and materials.

Finance
The Fiedlers put aside some cost considerations for this project in order to test the viability of several green products, many of which were new to the marketplace. In order to cut costs, the entire project’s labor was performed by Fiedler Designs LLC. The cost savings of Energy Star® appliances, the tankless water heater, a smaller lighting load, and greater long-term material durability may pay for themselves, but not for some time. It will benefit future customers to choose sustainable products and techniques as they become more mainstream.

Lessons and Trade-offs
The biggest surprises of this project were the durability and stability of No-Added Urea Formaldehyde (NAUF) composite casework products and the bamboo cabinets. The Fiedlers would urge others to consider rapidly renewable woods, fibers, and composites as opposed to traditional woods with long growing times, and also to avoid products with high-VOC and urea formaldehyde content. Seeking out higher production capacity fabricators to use similar green materials would cut some costs. One of the biggest trade-offs was the lack of LED lighting choices for different applications. The designer looks forward to when LED lighting is available at a reasonable cost for task lighting and overhead lighting.

“The entire project was a valuable learning experience, particularly in researching and working with new green materials: understanding which green materials to recommend for future clients.”

- Stephen Fiedler

Energy Star® refrigerator
List of Green Strategies

Energy Conservation
• Installed 14” round solar light tubes to bring in natural light
• Purchased Energy Star®-rated dishwasher, gas stove, refrigerator, and microwave
• Installed recessed hi-hat ceiling light fixtures with sealed, close contact insulation capability
• Used LED bulbs in high hat recessed fixtures
• Chose low-voltage lighting fixtures

Water Conservation
• Chose a two-handle kitchen faucet to minimize hot water demand
• Installed a tankless gas water heater
• Installed a reverse osmosis water purification system with a separate dispenser tap at sink
• Installed an under-mount stainless steel single bowl sink with a built-in drain board

Indoor Air Quality
• Used NAUF plywood for subflooring and cabinet case construction; NAUF bamboo materials
• Chose no-VOC paints for the walls, ceiling and trim
• Hazardous Air Pollutant (HAP) -free, no-VOC, water based finish on all cabinetry components

Sustainable Materials
• Chose bamboo products for cabinet doors, drawer fronts, side veneers, panels and case edging
• Installed recycled glass/concrete countertops
• Purchased engineered quartz secondary table tops
• Installed low-VOC natural linoleum flooring
• Installed insulation made from borate-treated shredded cotton blue jeans
• Tiled walls with 100 percent pre-consumer recycled content wall tiles
• Used 100 percent recycled wall board from power plant scrubber lime and recycled paper
Overview and Scope
This project involved the preservation and complete green renovation of a century-old historic carriage house at the Twin Maples Estate in Summit, New Jersey. The work was completed for the recent Twin Maples Centennial Show. The second floor apartment was fully renovated, as was the lower level foyer and all of the heating, cooling and water systems for the structure. The lower level bays were left intact to preserve their historic terra-cotta tile floors and mahogany bead board walls and ceilings. Wood insulated garage doors were added to improve energy efficiency in the lower level.

Design Approach
One of the most important aspects of sustainable building practice and design is the reuse of existing structures and materials; the renewal of this 100 year-old carriage house represents a prime example of how new life can be brought to a historic building. The designers wanted to demonstrate that green design could be practical and aesthetically pleasing. They aimed to create beautiful interior spaces using environmentally-friendly furnishings, reclaimed and renewable flooring, and energy-efficient appliances throughout the house.

Team and Process
Seven interior designers teamed up with architect Hiland Hall Turner and builder Roger Polo. The designers incorporated several themes, including natural colors and materials, circular patterns representing the natural cycle, and a juxtaposition of contemporary and rustic details. The concept was to reuse, recycle and use renewable and energy-efficient resources.

Finance
Polo Master Builders and their subcontractors donated the materials and labor necessary to renovate the carriage house. Hiland Hall Turner donated his architectural services. The designers and their suppliers donated the interior finishes. Perfection Contracting donated the installation of the new high-efficiency hybrid heating and cooling system.

Lessons and Trade-offs
The design team found that while many green products, such as energy and water-efficient features, are readily available, other environmentally friendly products may be more expensive and require more careful research. Product availability for certain spaces may be trickier than others due to lack of knowledge on the part of suppliers as well.

“We hope to inspire architects, builders and homeowners to take action to make historic buildings more sustainable by installing history-friendly and eco-friendly building materials, as well as state-of-the-art efficient energy systems.”
- Heidi Evenson, Co-Chairman, Twin Maples Centennial Show House
List of Green Strategies

Energy Conservation
- Installed Energy Star® appliances in the kitchen
- Installed a high-efficiency hybrid heating and cooling systems to heat and cool the apartment and lower level foyer
- Added blown-in insulation to the walls and attic space
- Added a new insulated hay loft door and two insulated garage doors to improve energy efficiency and add natural light to the interior

Water Conservation
- Installed low-flow fixtures in the kitchen and bathroom
- Installed a dual-flush toilet in the bathroom

Indoor Air Quality
- Installed formaldehyde-free cherry cabinets in the kitchen
- Used low-VOC paints throughout the structure
- Used a green product to finish the recycled barn wood floor

Resource Conservation
- Incorporated fixtures comprised of existing materials such as reclaimed wood and recycled aluminum
- Refurbished new items from recycled materials such as a stairway runner from an old conveyor belt, a lamp from a wrought-iron gate, a nightstand from a sewing machine table, and a writing desk from an old barn door
- The flooring throughout was reclaimed from a barn in West Virginia

Sustainable Materials
- Utilized renewable and recycled materials throughout the house, including recycled leather tiles, bamboo flooring, reclaimed barn wood flooring, recycled glass, natural carpeting and wall-covering materials (including hemp, straw, and sea grass)
Green Products and Services

Introduction

The purpose of the Green Products and Services is to help homeowners navigate the market with some helpful tips on what to look for when shopping for a particular green home remodeling project. The Guide is organized by building system and lists the general products and services that pertain to remodeling tasks within that system. It includes features and applicable certifications to look for, as well as web links to more information on that product or service. Each item in the Guide also refers to the related REGREEN strategy IDs.

Please note that the New Jersey Green Home Remodeling Guidelines Version 1.0 do not endorse any particular brand or company. It is not the function of the Green Product and Service Guide to direct the consumer to a specific product, but rather to provide a resource to seek out an appropriate manufacturer or service provider to handle remodeling needs.

With the ever-increasing number of green products and services coming into the home remodeling market, finding the appropriate ones can be a challenge. Some manufacturers market products as “green” when in reality they are only marginally better for the environment or whose green features are neutralized by other aspects of their manufacturing or composition. This phenomenon is referred to as “greenwashing” and calls on consumers to seek out references and ensure the true extent of green value.

Product Certification Programs

That being said, there are several leading green product standards and certification programs that can help consumers identify products that meet predefined green criteria. The leading green product standards and programs include:

- Energy Star® - identifies efficient products that reliably deliver energy savings and environmental benefits
- WaterSense – identifies high performing, water efficient products and practices
- Cradle to Cradle - certifies products based on lifecycle of materials used to construct a product and the overall lifecycle of the product
- GreenGuard® Certification Program - certifies products and processes for their low chemical emissions and low toxicity
- Green Seal® - certifies products and practices for their low toxicity and overall environmental impact
- GreenSpec Directory - a published resource on environmentally preferable products
- Forest Stewardship Council (FSC)- certifies wood products coming from forests managed to meet social economic and ecological needs
- Sustainable Forestry Initiative (SFI) - certifies wood products coming from well-managed forests and responsible procurement practices
- National Fenestration Rating Council® (NFRC) - a non-profit organization that administers the only uniform, independent rating and labeling system for the energy performance of windows, doors, skylights, and attachment products

For more information on various certification programs currently in use by architects and designers see:
- the ecolibrary™matrix - www.thegreenstandard.org/documents/GGNC09_EcoLibCert.pdf
- Gaia Product Profile developed by The Green Standard™ - www.thegreenstandard.org/gaia.html

Two other reputable sources for green products and services are:
- Green Building Advisor that lists products from the GreenSpec Guide to Residential Building Materials www.greenbuildingadvisor.com/
Product Standards for GreenSpec

1. Products Made with Salvaged, Recycled, or Agricultural Waste Content
   a. Salvaged products
   b. Products with post-consumer recycled content
   c. Products with pre-consumer recycled content
   d. Products made with agricultural crop waste material

2. Products That Conserve Natural Resources
   a. Products that reduce material use
   b. Products with exceptional durability or low maintenance requirements
   c. Certified wood products
   d. Rapidly renewable products

3. Products That Avoid Toxic or Other Emissions
   a. Natural or minimally processed products
   b. Alternatives to ozone-depleting substances
   c. Alternatives to hazardous products
   d. Products that reduce or eliminate pesticide treatments
   e. Products that reduce stormwater pollution
   f. Products that reduce impacts from construction or demolition activities
   g. Products that reduce pollution or waste from operations

4. Products That Save Energy or Water
   a. Building components that reduce heating and cooling loads
   b. Equipment that conserves energy and manages loads
   c. Renewable energy and fuel cell equipment
   d. Fixtures and equipment that conserve water

5. Products That Contribute to a Safe, Healthy Built Environment
   a. Products that do not release significant pollutants into the building
   b. Products that block the introduction, development, or spread of indoor contaminants
   c. Products that remove indoor pollutants
   d. Products that warn occupants of health hazards in the building
   e. Products that improve light quality
   f. Products that help noise control
   g. Products that enhance community well-being

**Features**

- **Electric Ignition Ranges:** More efficient than those with pilot lights.
- **Self-Cleaning Ovens:** More insulated and more efficient.
- **Induction Ovens:** Most efficient but expensive.
- **Convection Ovens:** Efficient and more affordable.

**Certifications**

- **Low Impact Living:** www.lowimpactliving.com/
- **Grist.org:** A Test of 8 Green Bathroom Cleaning Products www.grist.org/advice/products/2008/03/25/
ambient lighting  Ambient lighting uses warm lighting sources with a color temperature between 2700 - 3000K that is more flattering to skin tones and clothing. Recommended for living spaces.

ANSI/ASHRAE

ANSI  The American National Standards Institute oversees the activities of many industries in the United States to ensure competitiveness in the global marketplace, the health of consumers, and environmental protection.

ASHRAE  The American Society of Heating, Refrigerating and Air-Conditioning Engineers is an international organization whose mission is to advance the arts and sciences of heating, ventilating, air conditioning, and refrigerating to serve humanity and promote a sustainable world.

asbestos  Asbestos is the name given to a number of naturally-occurring, fibrous silicate minerals mined for their useful properties such as thermal insulation, chemical and thermal stability, and high tensile strength. Asbestos is commonly used as an acoustic insulator, and in thermal insulation, fire proofing and other building materials. Many products in use today contain asbestos.

awning  An awning is a constructed frame covered in a material that extends from an existing structure (usually the side of a house) to provide protection from the sun and rain.

backdrafting  Backdrafting occurs when a home becomes depressurized from air escaping to the outside and is replaced with air entering from the exterior. This air may contain combustion products including carbon monoxide.

Blower Door Test  The Blower Door Test measures the leakiness of the house or its air infiltration and helps a homeowner prioritize problem areas. This test uses pressure differences created by air flow via a calibrated fan that mounts on the frame of an existing door and pulls air out of the house, lowering the inside air pressure. As higher pressure outside air travels in through unsealed cracks and openings, tools like a smoke pencil can detect these air leaks as part of a visual inspection process.

brominated  Brominated materials are combined with Bromine, a heavy, volatile, corrosive, reddish-brown, nonmetallic liquid element, having a highly irritating vapor. Some of the materials include flame retardants, photographic chemicals, and dyes among others.

building envelope  The building envelope of a structure is descriptive term that separates its interior from the exterior.

carbon dioxide (CO₂)  Carbon Dioxide is a gas byproduct of the burning of fossil fuels and other forms of combustion.

carbon monoxide (CO)  Carbon Monoxide is a toxic gas byproduct of combustion that is both odorless and colorless. Sources of its production include wood stoves, fireplaces, gas stoves, and furnaces among others.

carbon/specialized media  Carbon or specialized media refers to the presence of bacteria that can be applied to a filtration system to remove certain pollutants.

cellulose  Cellulose fibers from recycled newsprint can be applied as a form of insulation resistant to flame, mold, and pests; provides thermal and sound insulation, and resists settling.

cellulose fiber  Cellulose fibers from recycled newsprint can be applied as a form of insulation that resist flame, mold, and pests; provides thermal and sound insulation, and resists settling.

cement board  Cement board is a non-combustible, water-durable, and mold-resistant panel that is typically used under tile and other finishes, for interior and exterior use.

certified sustainable wood  Certified sustainable wood meets specific criteria developed by organizations such as the Forest Stewardship Council to promote responsible wood harvesting and condemn the exploitation of local peoples.

Chlorinated Polyvinyl Chloride (CPVC)  Chlorinated Polyvinyl Chloride (CPVC) are thermoplastic piping materials used for such applications as water distribution, industrial fluid handling, and fire suppression systems.

Color Rendering Index (CRI)  The Color Rendering Index (CRI) is a 1-100 scale that measures how colors appear under different light sources. A light source with a CRI of 80 or higher is considered acceptable for most indoor residential applications.

combustion  Combustion is the chemical process of the release of gasses in the process of burning of a fuel.

combustion appliances  Combustion appliances burn fuels including stoves, water heaters, and clothes dryers. It is important to make sure that these appliances work correctly and are properly ventilated to prevent carbon monoxide, a byproduct of combustion, from entering the home.

combustion equipment  Combustion equipment refers to appliances that burn fuels including stoves, water heaters, and clothes dryers. It is important to make sure that these appliances work correctly and are properly ventilated to prevent carbon monoxide, a byproduct of combustion, from entering the home.

Compact Fluorescent Lights (CFLs)  Compact fluorescent lights are the miniature fluorescent lights that can screw into light fixtures that conventionally use incandescent bulbs. CFLs are more energy-efficient and durable than incandescent bulbs.

cross-linked polyethylene (PEX)  Cross-linked polyethylene is a plastic often used for water supply piping that is flexible, resistant to scale and chlorine, doesn't corrode, is faster to install, and has fewer connections and fittings than does metal piping or rigid plastic piping such as PVC, CPVC, and ABS.

diffuser  Diffusers are circular, square or rectangular air distribution outlets which are usually located in the ceiling. They are comprised of deflecting blades which discharge supply air in various directions. Diffusers are designed to mix the conditioned air entering the space with the air already contained in the space.

disposable respirators  Disposable respirators or filtering facepieces can be made of cloth or paper and are designed to clean the air as you breathe it to prevent you from inhaling irritating substances.

double-hung window(s)  Double-hung windows have two vertically sliding sashes, each closing a different part of the window.
double-pane window(s) Double-Pane Windows consist of two pieces of glass separated by an air space. The air space allows for less heat transfer between the interior and the exterior of the home, reducing heating and cooling loads.

drain pan Drain pans are installed to catch any fluids leaking from a piece of equipment such as a clothes washer.

Duct Blaster Test A duct blaster utilizes a fan and a pressure gauge to measure the amount of air escaping from the ductwork of a home by pressurizing the system.

duct cleaning Duct cleaning refers to the cleaning of heating and cooling system components in forced air systems, including the supply and return-air ducts, registers, grilles, diffusers, heat exchangers, heating and cooling coils, drain pans, fan motor, fan housing, and the air handling unit.

electrochromic Electrochromic windows can convert from being transparent to tinted via an electrical switch, or a sunlight or temperature sensing detector that applies an electrical charge to the window. These window systems can control the amount of light and solar energy that pass through providing control over daylighting, glare, solar heat, and protection from harmful ultraviolet (UV) rays.

endocrine system The endocrine system regulates the release of hormones throughout the body. They control metabolism, growth and development, mood, and tissue function.

energy performance rating Energy performance ratings indicate the potential for heat transfer and sunlight transmittance of windows, doors, and skylights.

Energy Star® Label The Energy Star label appears on appliances that meet the standards developed by the United States Environmental Protection Agency of energy, water and other resource conservation.

Environmental Protection Agency (EPA) The United States Environmental Protection Agency conducts research, educates, and assesses issues in environmental science to promote human health and a healthy environment.

fire retardants Fire retardants are chemicals used to prevent or resist the spread of fire.

flame retardants Flame retardants are non-combustible materials that resist the spread of fire.

flashing Any piece of material, usually metal or plastic, installed to prevent water from penetrating the structure.

formaldehyde Formaldehyde is a chemical compound used in products including paper towel, photographic film, glues, and inks among others. It is important to avoid products containing formaldehyde whenever possible as they off-gas potentially hazardous pollutants.

Forest Stewardship Council (FSC) The Forest Stewardship Council (FSC) is an independent, non-governmental, not-for-profit organization established to promote the responsible management of the world’s forests.

Forest Stewardship Council (FSC)-Certified Wood The Forest Stewardship Council certifies wood that complies with its standards, disapproving of illegally harvested wood, wood harvested in violation of traditional and civil rights, in forests in which High Conservation Values (areas particularly worthy of protection) are threatened through management activities, from conversion of natural forests, and from areas where genetically modified trees are planted.

glazing Window glazings are compounds applied to glass to reduce the amount of heat transfer between the interior and the exterior of a building and/or the ultra-violet (UV) light passing that passes through it.

grille Grilles are vent covers that are normally used on air return ducts. Grilles do not have a pre-attached damper. Louver assemblies can be used with grilles so that the grilles can be used on forced air ducts and still provide airflow control.

gypsum Gypsum is a mineral found in sedimentary rock formations in a crystalline form known as calcium sulfate dihydrate. It is typically used in wall board to create a non-combustible core.

gypsum board Gypsum board or drywall is used in various paneling applications that consist of a paper-faced non-combustible gypsum core.

H-axis machines Horizontal-axis (H-axis) or front loading washing machines use less water by dipping clothes into the water at the bottom of their basins as they rotate.

heat exchanger(s) Commonly used in space heating, refrigeration, air conditioning, and other applications, heat exchangers are devices built for efficient heat transfer from one medium to another.

Heat-Recovery Ventilator (HRV) Heat-recovery ventilators are air circulation systems that minimize the amount of heat that gets lost as air is transferred between the interior and exterior of a home, saving energy.

heating and cooling coils The heating and cooling coils of an appliance or piece of machinery converts electricity into heat energy.

heating load Heating load refers to the amount of heat it takes to maintain the temperature of an indoor space.

Heating, Ventilation, and Air Conditioning (HVAC) Systems Heating, Ventilating, and Air Conditioning systems process and supply air through ductwork helping to regulate humidity and temperature in buildings to provide safe, healthy, and comfortable conditions.

heavy metals Heavy metals including copper, selenium, and zinc are elements found in the earth’s crust that can’t be degraded or destroyed. Some in small doses are vital to bodily functions while high concentrations can be lethal.

HEPA filtered air scrubbers High efficiency particulate air or HEPA air filters are a type of high-efficiency air filter that remove at least 99.97% of airborne particles down to a size of 0.3 micrometers (µm) in diameter.

HEPA vacuum High efficiency particulate air or HEPA filters are a type of high-efficiency air filter that remove at least 99.97% of airborne particles 0.3 micrometers (µm) in diameter. HEPA filter
used in vacuum cleaners trap the fine particles (such as pollen and dust mite feces) which trigger allergy and asthma symptoms.

**High-Density Polyethylene (HDPE)** High-density polyethylene (HDPE) is a thermoplastic used to make milk bottles, packaging containers, toys and other products because of its resistance to most chemicals, high impact tensile strength, and insolubility in organic solvents.

**Home Performance Audit** Home Performance Audits are conducted to assess the energy efficiency of a home and evaluate possible energy saving measures.

**Home-run piping system** Home-run or manifold plumbing systems utilize both PEX piping and a manifold. The system is characterized by direct lines from the manifold to any fixtures thus reducing the amount of water needed and provides hot water faster.

**HUD** The United States Department of Housing and Urban Development is a cabinet-level department that was created in 1965 to increase home ownership, support community development, and increase access to affordable housing free from discrimination.

**IICRC S500 Guidelines** The Institute of Inspection, Cleaning and Restoration is an independent, non-profit certification body that sets and promotes standards for the inspection, cleaning and restoration service industry. These guidelines provide specific practical standards for water damage restoration.

**Indigenous** Indigenous peoples are descendents of the earliest known inhabitants of a particular geographic region.

**Infrared camera technology** Infrared camera technology is used to detect thermal variations and may be used in conducting energy efficiency analyses.

**Jute** Jute is a glossy plant fiber used to make sacks, rope, twine, and other materials.

**Kelvin** Kelvin is a universally accepted base unit used to measure temperature. One degree in Celsius is equivalent to one degree in Kelvin. Water freezes at zero degrees Celsius, which is approximately 273.16 Kelvin.

**Light-Emitting Diode (LED)** Light Emitting Diodes are electronic light sources that use less energy than incandescent bulbs or compact fluorescent lamps.

**louver(s)** Louvers are vertical slats on a window, blind, or shutter that are angled in such away to allow in light and air while providing a shield from rain, direct sunlight, and noise.

**low-E** Low-E or Low-Emissivity glazings are metal or metal oxide coatings applied to windows to reduce heat flow.

**low-VOC** These products contain smaller amounts than standard materials of volatile organic compounds (VOCs) that can off-gas chemicals and cause air pollution.

**Modified Energy Factor (MEF)** is a combination of Energy Factor and Remaining Moisture Content (RMC). MEF measures energy consumption of the total laundry cycle (washing and drying). It indicates how many cubic feet of laundry can be washed and dried with one kWh of electricity; the higher the number, the greater the efficiency.

**moisture meter** Moisture meters are devices used to measure the amount of water in a given substance that help determine if it is ready to use.

**mold amplification sites** Mold amplification sites are locations where mold has built up over time. Typical sites of indoor mold buildup are damp cellulotic materials (e.g. wallboard paper, wallpaper, carpet backing, damp papers); debris in ventilation ducts, in carpets, or in mattresses or upholstered furniture; poorly maintained humidifiers; insulation on which organic film has accumulated; constantly humid painted, caulked or plastic surfaces (e.g., windowsills, shower stalls, cold air return vents); and potted plant soils.

**mortar** Mortar is a sandy material that combines with cement and water to bond tile, stone, brick, or concrete blocks.

**National Air Duct Cleaning Association (NADCA)** The National Air Duct Cleaners Association (NADCA) was formed in 1989 as a non-profit association of companies engaged in the cleaning of HVAC systems. Its mission was to promote source removal as the only acceptable method of cleaning and to establish industry standards for the association.

**National Fenestration Rating Council (NFRC)** The National Fenestration Rating Council (NFRC) is a non-profit organization that administers the only uniform, independent rating and labeling system for the energy performance of windows, doors, skylights, and attachment products.

**off-gassing** Off-gassing is a release of chemical materials due to evaporation and may release potentially hazardous gases.

**passive heating** Passive solar heating systems transfer sunlight into heat energy that can be used to warm building interiors.

**petroleum-based** Petroleum-based products are made from the raw natural resource petroleum, such as oil and natural gas.

**phantom load** The phantom load refers to the electricity being used by an appliance when it is turned off but still plugged into an outlet.

**plasticizers** Plasticizers are additives that increase a materials workability, flexibility, or pliability.

**Polyvinyl Chloride (PVC)** Polyvinyl chloride is a plastic commonly used as piping that is capable of off-gassing harmful chemicals.

**porous** Porous materials have spaces through which gases and/or liquids can pass.

**post-consumer recycled content** Post-consumer recycled products consist of materials that were previously used by consumers.

**power-vented combustion** Power-vented combustion appliances have fans that draw combusted air outside.

**pre-consumer recycled content** Pre-consumer recycled materials consist of industry scraps.

**Radon** Radon is a carcinogenic (cancer-causing) radioactive gas produced from the decay of uranium in rock, soil, and water.
reclaimed materials  Reclaimed materials are salvaged architectural components that save money, are better for the environment, and are aesthetically pleasing.

reclaimed wood  Reclaimed wood is salvaged lumber that can save money, is better for the environment, and is aesthetically pleasing.

recycled content  Products with recycled content are made from materials that have already been used in another product.

registers  Registers are vent covers that are typically used on forced air ducts. They have a pre-attached damper or set of louvers to help control airflow.

return air duct  Return ducts prevent the pressurization of closed rooms from supply air by allowing air to flow black to the central return grille.

reverse osmosis  Reverse osmosis is a filtration process that forces a liquid through a membrane allowing only the pure solvent to pass.

R-Value  The R-value of a material indicates its resistance to heat transfer. A high R-value is better than a low R-value.

sash  Window sashes consist of the moving section(s) of a window.

sealed combustion  Sealed combustion appliances only use air from the outside and directly vent the combustion air back outdoors.

sheathing  Sheathing refers to a building material that is used to cover exterior wall framing or roof trusses.

single-pane windows  Single-paned windows have only one piece of glass separating the interior and exterior of a home. Double-pane windows are considered to be much more energy-efficient.

single throw shut-off valve  Single throw shut-off valves can prevent flooding by turning off the supply of water should a clothes washer hose malfunction.

sisal  Sisal is a plant that produces stiff fibers for applications such as rug or twine making.

Solar Heat Gain Coefficient (SHGC)  The Solar Heat Gain Coefficient is the fraction of incidental solar radiation admitted through a window.

solar tube(s)  Solar tubes consist of a clear dome that collects sunlight into a highly polished and reflective tube that reflects the light down to a diffuser on the ceiling. They are sufficient enough to light a small room, hallway, or staircase.

solvent  A solvent is a liquid substance capable of dissolving other substances.

sones  Sones are a measure of loudness.

storm door  Storm doors consisting of a combination of glass and screens can be used to increase the energy efficiency of an exterior doorway.

storm window  Storm windows are pieces of glass or plastic mounted to the interior or exterior of an existing window that serve to reduce the amount of airflow in and out of a home, reducing heating and cooling loads.

supply duct(s)  Supply ducts made of formed sheet metal deliver air to interior spaces from an HVAC system.

task lighting  Task lighting, often described as “cool” lighting, produces higher contrasts that are better for seeing. Task lighting sources emit temperatures between 3600-5500K.

terpenes  Terpenes are found in nature usually as the essential oils of certain plants that are used in fragrances, food additives, and other products.

transom  Transoms are the windows above doors that serve to allow in sunlight and release warm air.

U-Value  The U-value or U-factor of a window assembly indicates its rate of heat loss. The lower the U-value the better.

Ultraviolet (UV) radiation  Ultra-violet Light (UV) is defined as electromagnetic radiation in the spectral region between 180 and 400 nanometers. Prolonged exposure to UV light can result in sunburns, skin cancer, and the fading of certain materials.

ultraviolet treatment  Ultraviolet water treatment systems utilize a mercury lamp that exposes water to UV rays to through a chamber that kills any bacteria. The system doesn’t add any taste or odor to the water and should only be used with clear water.

urea-formaldehyde-free  Urea-formaldehyde-free products lack any urea formaldehyde content known to off-gas harmful pollutants.

virgin materials  Virgin material is made exclusively with raw materials and contains no recycled content.

vitrified clay  Vitrified clay pipe (VCP) is a sustainable sewer piping material.

Volatile Organic Compound(s) (VOC)  Volatile Organic Compounds (VOCs) are off gassed from certain solid or liquid products that when exposed to them may cause negative health effects.

Water Factor (WF)  Water factor is the number of gallons needed for each cubic foot of laundry. A lower number indicates lower consumption and more efficient use of water.

Water Sense® labeled  Water Sense labeled equipment meets specific water efficiency and performance criteria established by the U. S. Environmental Protection Agency.

weatherstripping  Weatherstripping is the sealing of cracks or holes around windows, doors and other openings exposed to the exterior of a building with caulk, foam, rubber strips, or other materials that can be used to reduce airflow between the interior and the exterior.

whole house fan  Whole house fans located on attic floors ventilate warm air from interior spaces to the outside while depressurizing the home to draw in cool air from open windows.

zero-VOC  Zero-VOC products contain no volatile organic compounds and thus do not negatively impact air quality from off-gassing chemicals.
Increasing the livable space in the homethrough finishing the basement or adding a new addition provides an excellent opportunity to incorporate green home remodeling. In basement remodeling and additions, ensuring indoor environmental quality through radon reduction and moisture control is paramount. Before embarking on a do-it-yourself remodel, consider consulting with a professional who can help ensure implementation of proper green design techniques. Selecting green options for basements and major additions requires a bit of research, but the overall benefits of better insulation, ventilation, and finishes cannot be understated.
Finished Basement and Major Addition

How to Use the Guidelines

Health and Safety
- HS1 - Nuisance and Toxic Dust Control
- HS2 - Cautious Materials - Asbestos & Lead
- HS3 - Mold
- HS4 - Radon

Green Home Maintenance and Housekeeping

Site
- Configure for solar access [EA100]
- Consider on-site renewable energy [EA102]
- Minimize site disturbance [SS29]
- Landscape for passive heating and cooling [SS30-31/36]
- Maintain slope to drain away from building [IDP13]
- Minimize impervious surfaces [SS32]
- Landscape to minimize heat island effects [IDP17]
- Plan for erosion control [SS39]

Foundation
- Test and install a radon mitigation system [IEQ163]
- Insulate floor slab and foundation walls [EA47]
- Provide moisture control at foundation [IDP19]
- Utilize Integrated Pest Management [IDP23]
- Use biobased form-release agents [MR115]
- Use fly ash in concrete [MR114]

Building Envelope
- Conduct a Home Performance Audit and diagnostic tests [IDP2/EA51-54]
- Minimize wood use with advanced framing [MR116]
- Install or upgrade insulation [EA49]
- Install a durable wall cladding [MR119]
- Air seal to reduce infiltration [IDP55]
- Include capillary break [IDP22]
- Provide moisture management strategies [IDP24]

HVAC
- Follow standards for mechanical design [EA63]
- Provide controls and zoning for HVAC [EA64]
- Select high-efficiency HVAC equipment [EA66]
- Install programmable thermostats [EA67]
- Conduct duct tightness test [EA68]
- Maintain HVAC systems [EA69]
- Seal and insulate HVAC system [EA70]
- Make sure ductwork is clean [EA71]
- Use ceiling fans for natural ventilation [EA65]

Plumbing
- Insulate water heater [EA80]
- Insulate hot water pipes [EA81]
- Utilize solar water heating [EA101]

Lighting and Electrical
- Plan for future wiring and cabling needs [MR121]
- Provide daylighting [EA83]
- Provide appropriate lighting [EA84]
- Install energy-efficient lighting [EA85]
- Provide appropriate indoor lighting controls [EA90]

Wall and Ceiling
- Use non-paper-faced gypsum board in moist areas [IEQ183]
- Install eco-friendly interior sheathing [MR126]
- Choose eco-friendly paints, sheens, and finishes [IEQ185/MR130-131]
- Select eco-friendly wall coverings [MR129/IEQ186]

Furniture and Fittings
- Select eco-friendly furniture [MR141-143/146-147/150]
- Choose eco-friendly furniture [MR141-143/146-147/150]

Use
- Select materials that are easy to clean [MR156]

Case Studies

Green Products and Services

Glossary of Terms
How to Use the Guidelines

Organization of the Guidelines

The Guidelines are organized into chapters by major project type: Kitchen, Bath and Living Spaces, Finished Basement and Major Addition, Weatherization and Energy, and Outdoor Living and Landscaping.

Each chapter includes the following:

• How to Use the Guidelines
• Health and Safety
• Green Home Maintenance and Housekeeping
• Best Practice Strategies
• Resources and References
• Case Studies
• Green Products and Services
• Glossary of Terms

Getting the Most from the Strategy Write-ups

The Guidelines provide information on best practice strategies for each project type. These strategy write-ups are organized by building system and follow the order of the 2008 REGREEN Residential Remodeling Guidelines (i.e., IDP2), which are incorporated with permission. Figure 1 describes the information available.

*Figure 1*

**Title**

**REGREEN ID**

**Shopping Cart**

**Call-out Box**

**A Home Performance Audit** identifies energy upgrades for cost savings. Diagnostic tests examine the whole house and look at the interactions between all systems in a home: air leakage, insulation, combustion appliances, heating and cooling systems, and ventilation. Several free online energy audit tools are available for homeowners. The NJ Office of Clean Energy's Home Energy Analysis Tool offers specific recommendations based on the age of the home; average energy usage, the types of appliances, and other criteria. It is available on the NJ Office of Clean Energy website: www.njcleanenergy.org.

**Scorecard**

**Strategy Description**

**Glossary Term**

**REGREEN ID** – The strategies in the REGREEN Residential Remodeling Guidelines 2008 inspired most of the strategies in these Guidelines. Where appropriate, the strategy references the related REGREEN strategy ID.

**Shopping Cart** – The cart denotes entries in the Green Product and Service Guide located in the back of each project chapter.

**Strategy Description** – This write-up provides an overview of each strategy and its environmental benefits.

**Glossary Term** – Acronyms and green building terms are highlighted in bold and defined in a glossary at the back of each chapter.
Call-out Boxes - The call-out boxes in Figure 2 highlight information of special importance. These include the following types of information:

- **Tips** - useful hints or practical facts for accomplishing a strategy
- **Incentive** - sources of financial assistance
- **New Jersey Bio-Region** - New Jersey has 5 bio-regions, each with unique elements and environmental features to consider when remodeling
- **Building Age** - a home’s age can inform needed repairs and call out special circumstances
- **Caution** - on occasion, there are hazards associated, so items are called out for safety reasons

Hazard Symbol - Symbols were developed to advise users of certain health and safety threats related to specific strategies. The symbols, which appear below, reference the guidance on Health and Safety located at the beginning of each section.

- **HS1 – Nuisance and Toxic Dust Control**
- **HS2 – Hazardous Materials - Asbestos & Lead**
- **HS3 – Mold**
- **HS4 – Radon**

Web Link - When viewing this document electronically, the websites will hyperlink, however, occasionally website links change. In most cases, the site provides a seamless link to the new address. If this is not the case, users may need to copy and paste the link into the browser address bar. At the time of publication the hyperlinks in this report were all functional.

Scorecard - The scorecard, Figure 3, provides a snapshot of the environmental benefits, initial costs, and difficulty levels associated with a particular strategy. Both qualitative and quantitative information was used to assign scores to each strategy.

It is divided into two parts: 1) Benefits and 2) Feasibility.

Graphic icons were developed for each impact category.

**BENEFIT Key**

1 icon = low benefit, 2 icons = medium benefit, 3 icons = high benefit

**FEASIBILITY Key**

$ low initial cost, $$ medium initial cost, $$$ high initial cost

low difficulty level, medium difficulty level, high difficulty

The icons above have been developed to graphically describe the ratings that follow.

**BENEFITS**

- **Energy Savings**

To help meet its greenhouse gas reduction responsibility, in 2007 New Jersey passed carbon dioxide (CO₂) reduction goals, i.e., achieve 1990 emission levels by 2020, followed by a further reduction of emissions to 80 percent below 2006 levels by 2050. The state has also established renewable energy and energy efficiency targets. Green remodeling strategies utilize renewable energy sources such as solar, geothermal, and wind to net a lower CO₂ footprint.
Water Savings

Water conservation reduces water use both inside and outside the home. Within the home this may include low-flow fixtures. Outside the home this may refer to using native plants that have lower watering requirements or rain barrels to collect rainwater for reuse on the lawn and garden. Water management includes providing proper moisture control at footings, slab perimeter, and foundation walls as well as using porous paving materials to encourage stormwater recharge for reduced runoff.

Air Quality

Americans spend up to 90 percent of their time indoors where air quality can be more polluted than outdoors. Pollutants range from allergens such as mold, mildew, fungus, and dust mites to toxins, such as asbestos, and volatile organic compounds like formaldehyde and benzene found in building materials and a number of household items including pressed-wood furniture, computer ink, carpeting, and conventional household cleaners and cosmetics.

Resource Conservation

Resource conservation means using materials that are durable and easy to maintain with low embodied energy (the energy used in resource extraction, manufacturing, shipping). These come from renewable sources or are produced from waste, recycled materials, or salvaged from other uses. Avoiding building materials that deplete natural resources, such as old-growth timber, and materials made from toxic or hazardous substances improves nature’s ability to provide goods and services.

FEASIBILITY

$ Initial Cost

Cost is always a consideration for remodeling projects. Evaluating the cost of a recommended green remodeling strategy provides homeowners with a better sense of the relative costs and benefits of each recommended measure.

Costs come in two forms, so it is important to consider both in assessing feasibility. The first reflects initial costs of the strategy compared to conventional practices. A second consideration to make is the pay-back period or life-cycle cost. The pay-back costs are less obvious and are often project specific, but they can have significant environmental and economic value that factor into the overall cost. For more information on average costs, savings, and payback periods of typical energy efficiency improvements, see the Energy Efficient Rehab Advisor at (www.rehabadvisor.pathnet.org/). For customized results, have an energy professional conduct a thorough energy audit of your home.

- Less than $500
- $500-$5,000
- Greater than $5,000

† Difficulty Level

Time is money and expertise is gained over time. Some people may consider a Home Performance Audit strategy in the ‘medium’ category because although relatively straightforward to act on, it requires experts with custom equipment to prepare an accurate assessment. Implementing the findings from a Home Performance Audit becomes a ‘high’ difficulty category as space heating and cooling systems, ventilation, water heating, appliances, climate and even site factors need to be integrated to assure desired energy improvements across ‘ALL loads’ and to avoid negative unintended consequences. It is expected that ‘high’ difficulty strategies may also be dangerous for the basic homeowner to undertake.

† Easy to Do It Yourself (DIY) - little previous knowledge necessary

† † Task for an Experienced DIYer or Professional - may require additional effort and higher learning curve than conventional strategy it replaces

† † † Task for an Expert/Certified Professional - high learning curve; new technique; requires specific green knowledge

Health and Safety

Green remodeling poses hazards typical of many other home renovation or remodeling projects because of the age of the homes (given that they are more likely to contain older and use more hazardous materials) and the incentive for green remodeling to replace older or damaged building systems.

New Jersey homeowners considering green remodeling should anticipate potential emissions of hazardous air contaminants during removal of old building materials. The risks associated with improper removal of materials containing asbestos, lead, mold or even fiberglass insulation are minimized by understanding and following the steps listed here prior to initiating work. For complex situations, consider hiring professionals.

General hazard recognition and risk reduction information for the following potential renovation-related risks are contained in this section:

**HS1 – Nuisance and Toxic Dust Control**

Construction projects involving demolition of existing sheetrock, plaster, wood, brick or concrete products in ceilings, walls or floors of a home will release dust as these materials are ripped, sanded, ground, pulverized or crushed. Control of dust emissions during the pouring of solids or from transferring of small particles is controlled in industrial facilities. Homeowners planning renovation projects should also consider steps to minimize the release and maximize control of dust in the environment. These nuisance dusts, when released from the point of origin into the air of the home, tend to remain suspended in the air for very long periods of time, and as such, will be transported with air currents caused by open doors, cracks around and beneath doorways, forced air heating and cooling ductwork, and even by the air currents caused by persons walking in and out of dusty areas, to other areas of the home. At a minimum, allowing the uncontrolled release of nuisance dusts from any demolition project, as well as those created from sawing, sanding, or grinding of newly constructed materials (e.g., sheetrock, spackling, wood dust etc.) presents unnecessary and difficult dust cleanup demands for affected living spaces. At their worst, susceptible occupants of homes where uncontrolled nuisance dusts are allowed to escape into adjacent living spaces may temporarily experience eye, nose, or throat irritation. Asthmatics may experience adverse respiratory distress when exposed to high levels of nuisance dust particles.

There are several simple steps to minimize potential hazards of nuisance dust during remodeling.

1. Remove unnecessary porous and non-porous materials (e.g., draperies, bedding, upholstered furniture, children’s toys, clothing, etc.) from the project area.
2. Seal the project area from the remainder of the home using polyethylene sheeting at doorways and at inlets to any forced air supply or return registers within the project space.
3. Consider installing HEPA filtered air scrubbers in the project area and discharging the exhaust air through an adjacent window using a tight fitting flexible duct through a sealed window opening (consider surrounding security requirements). Use a lightweight section of facial tissue at the doorways to confirm that air pressure is moving from the clean adjacent living space and into the project area (not the other direction) so that air leaks from the clean home into the dirty renovation area. This will reduce any potential for dusts from the renovation area to enter the adjacent areas of the home.
4. Periodically during the work session and after every work session, HEPA vacuum the renovation area following renovations to remove accumulated surface dust, without re-suspending it into the air.
HS2 – Hazardous Materials - Asbestos & Lead

When removing old building materials, know that they contain hazardous materials, which while intact present little to zero risk to occupants, but when removing can create airborne emissions and increase health and safety risks. This is especially true of asbestos and lead, and, possibly to a lesser extent, fiberglass. Removal of asbestos, lead or fiberglass needs to be planned and conducted with care to minimize exposures to airborne dust from these materials.

Asbestos

Asbestos is a mineral that has been mined in the U.S. since the early 1900’s. Its superior heat resistance properties, combined with its lightweight, high-tensile strength, and non-corrosive qualities, made it an ideal building material for buildings constructed between 1940 and the late 1980’s. Asbestos was banned as a building material in the U.S. after scientists concluded studies linking long-term occupational exposures to damaging respiratory health including asbestosis (scarring of the lung), lung cancer, and mesothelioma (cancer of the lining of the lung). Because intact asbestos presents no increased health risk, there is no requirement for removing it from existing homes. However, when it is disrupted, pulverized or suspended in air, the potential for inhalation of asbestos fibers increases risks of exposure. While health effects develop only after decades of long-term occupational or environmental exposure, homeowners should take particular care to prevent unintentional release of asbestos into the air of their homes during green remodeling efforts so that children and others are not exposed.

Asbestos is commonly found in older homes (constructed between 1940 and the late 1980’s) in the following building materials:

- Pipe and boiler insulation
- Sprayed on fireproofing insulation
- Acoustical tiles and wall coverings
- Floor tiles
- Roof shingles
- Siding shingles

There is no requirement that homeowners remove asbestos-containing materials from homes. However, if removal is part of a green building remodeling project, material should be tested by a New Jersey licensed asbestos control monitor, and if determined to contain asbestos, be removed by a New Jersey licensed asbestos contractor. The number of the state program to contact for assistance in identifying qualified personnel to assist homeowners to safely address any possible asbestos concerns is (609) 292-7837. General information about asbestos and its proper management and disposal can be found at the Department of Health website: www.state.nj.us/health/iep/asbestos.shtml and the Department of Environmental website: www.nj.gov/dep/dshw/rrtp/asbestos.htm.

Lead

Lead was in residential paints prior to 1978. It was banned after that time due to the significant health affects to children inhaling or consuming dusts from lead-based paints. Because of the hazards posed by dusts and chips of lead-painted surfaces, any remodeling or renovation which impacts painted surfaces of homes constructed prior to 1978 needs to be inspected by a New Jersey licensed lead inspector. If lead paint is identified, it should be safely removed by a state of New Jersey licensed contractor. They can safely remove lead-based paint and conduct follow-up surface lead testing to confirm that the removal was successful. Information on lead-based paint and qualifications for lead inspectors and contractors can be found at: www.state.NJ.us/health/iep/documents/pb_advisory_bulletin.pdf.

Contact the New Jersey Department of Health and Senior Services at (609) 292-7837 with any questions.

Fiberglass

Fiberglass insulation is a manufactured glass-wool-like material used as an insulation and sound absorption material in homes, schools, automobiles and consumer products since the 1970’s. Fiberglass insulation can be safely installed if handled properly; any prolonged skin, eye or respiratory contact with fiberglass can cause temporary irritation. During renovation, wear loose fitting clothing and gloves to reduce skin contact, eye glasses or goggles to reduce eye exposure, and N95 disposable respirators (available from any home improvement store) if high levels of fiberglass dust are expected during removal or installation. More information on fiberglass safety precautions and handling recommendations can be found at the American Lung Association website at: www.lungusa.org/site/pp.asp?c=dvLUK9O0E&b=35439 or call the American Lung Association in New Jersey at (908) 687-9340.
HS3 – Mold

Mold contamination of building materials is not limited to older homes. Homes of any age can develop mold if moisture from leaky pipes, roofs, foundations, accumulates in the presence of dust, wood, paper or other cellulose-containing materials at normal room temperatures or high relative humidity (76 percent) for as little as 48 hours. Standing moisture around building materials such as wallboard, carpets, insulation, wood or other cellulose containing materials can cause mold. Many mold spores are known human allergens and produce toxins which may cause irritation or central nervous system effects. Because of vast differences in susceptibility, or if individual health impacts related to elevated mold spore exposure are of concern, consult a trained and experienced occupational/environmental health physician.

In addition to the above, mold damage can occur if flooding from faucets, showers, toilets (above the trap), is not completely dried within 48 hours of the incident. Floods from dirty water sources such as washing machines, dishwashers or sewers may contain high levels of bacteria, viruses, and protozoa which, along with potential mold growth, present additional risks.

If mold amplification sites occur, remove the affected material using methods that prevents unintentional dispersal of mold spores and the source of moisture intrusion. The U.S. Environmental Protection Agency indicates that small areas of mold growth (less than 10 square feet) can be cleaned or removed by homeowners themselves using precautions to prevent exposure and reduce spread of spores to adjacent areas. When mold contaminated areas exceed 10 square feet, special precautions including erecting containment barriers and the use of specialized HEPA vacuum devices should be used by trained professionals. When mold contamination occurs in excess of 100 square feet, professionals need to clean using full containment of the area (see www.epa.gov/mold/moldguide.html).

If mold growth from dirty water floods occurs, take special precautions to prevent skin, eye, oral and inhalation contact, and hire trained professionals to clean up in accordance with U.S. EPA: www.epa.gov/iaq/flood/index.html and IICRC S500 guidelines.

Homeowners should anticipate that the amount of mold contamination shown on the outside of a piece of drywall or paneling may be less than the amount that will be exposed when wall cavities are opened up. If there is any doubt, consider hiring a professional Certified Industrial Hygienist (CIH) to evaluate the extent of damage before attempting to remove contaminated building materials yourself.

HS4 – Radon

Radon is a radioactive gas that comes from the natural decay of uranium in the ground. It is odorless, tasteless and invisible, and can only be detected through specialized tests. Radon enters homes through openings such as cracks and joints in the foundation, sump pits and openings around pipes. The home traps radon inside and it can build up to high levels.

Radon is the second leading cause of lung cancer in the United States, resulting in 15,000 to 22,000 deaths annually. It is the leading cause of lung cancer for non-smokers.

Radon concentrations can vary from house to house. The radon concentration in a home depends on a number of factors, including the amount of uranium present in the soil, the permeability of the soil, the number of openings in the foundation and air pressure differentials. Any home can have a radon problem, regardless of whether it is old or new, well sealed or drafty, or with or without a basement.

The New Jersey Department of Environmental Protection recommends radon testing for all homes in New Jersey. If the radon concentration is 4 pCi/L or higher, a radon mitigation system is recommended. There is no safe level of radon since lung cancer can result from very low exposures to radon, however, the risk decreases as the radon concentration decreases. If the radon concentration is less than 4 pCi/L, a mitigation company can be consulted to determine whether the radon level can be brought down still further. Radon levels have been brought to less than 1 pCi/L in sixty percent of the homes mitigated in New Jersey. Mitigation systems can also help reduce the potential for accumulation of volatile organic compounds that may be released from soil water vapor in areas where ground water contamination is an issue.

Radon test kits are commercially available at most home improvement stores, however, test conditions and locations may make data interpretation difficult or inaccurate. Carefully follow the kit directions to ensure proper use and confidence in the results. The New Jersey Department of Environmental Protection has issued licensing requirements for radon testing firms, and has a list of qualified professionals to perform radon testing and mitigation, see www.njradon.org.

Green Home Maintenance and Housekeeping

Introduction

Your home is one of the biggest investments of your life. Can ‘going green’ protect your investment and make it safer, more enjoyable and save you money? Yes.

This guide to Green Home Maintenance and Housekeeping practices will improve the health, comfort and environment for your family, and save you money, most directly by reducing your utility bills. The guide’s focus on ‘Energy’ savings, improvements to ‘Indoor Air Quality’, effective and efficient ‘Household Waste Management’ and conserving ‘Water’ all add measurable benefits to you and high return on your investment. Routine checks and repairs will ensure your home’s appearance and proper function. By following these recommendations, you will also prevent more expensive damage from occurring.

Finished Basement and Major Addition

The biggest challenge in basement maintenance is to prevent or resolve moisture problems. Any major addition or renovation work requires good selection of materials and use of sound construction techniques.

1. Preventing and solving basement water problems:
   - Use basements as living spaces only if they are leakproof and well ventilated
   - Use a dehumidifier in the basement to maintain humidity between 30 to 50 percent
   - Improve the ventilation in the basement.
   - Install a sump pump and check on the valve working
   - Keep a check on the roof gutters and downspouts and extend the downspout extension away from your home
   - Maintain the slope of your yard so that it causes rainwater to flow away from your home.

2. Use environment friendly materials for all improvements:
   - Use low-emitting and VOC free materials (interior sealers, adhesives, paints and insulation) for any repair work
   - Ask about formaldehyde content of pressed wood products, including building materials, cabinetry, and furniture before you purchase them
   - Do not remove lead paint yourself. Do not dry scrap, sand or burn off paint that may contain lead
   - Reduce exposure to asbestos; when you need to remove or clean up asbestos, use a professionally trained contractor. Do not cut, rip or sand asbestos-containing materials
Configure for solar access [EA100]

Orientation dramatically affects the energy efficiency of the building envelope. While existing structures cannot be reoriented, new additions can consider orientation and the potential for solar energy features, including passive-solar heating, daylighting, solar water heating, and photovoltaic (PV) power production. Passive solar design provides an integrated approach to addressing a building’s heating, cooling, ventilating, day lighting, and electric needs.

The passive solar house is an energy-conserving house. Address energy leakages during a remodeling effort by conducting an Home Performance Audit before considering solar options as conserving energy is always the most cost-effective strategy.

Consider on-site renewable energy [EA102]

Ongoing advances in solar and geothermal technologies coupled with broader government financial incentives have made on-site renewable energy increasingly more feasible for the homeowner. Providing some or all of the home's energy from on-site renewable sources is an excellent way to not only significantly reduce utility bills, but also decrease one’s reliance on and consumption of traditional fossil fuel energy sources.

Due to the increasing number of incentives for solar equipment, a homeowner can install a photovoltaic array with smaller up-front costs and a quicker payback period. New Jersey maintains a Solar Renewable Energy Certificate (SREC) program that allows participants to receive sellable credits for the energy that they produce; each time a system generates 1000 kWh of electricity, a SREC credit is issued to the program participant. Also, all equipment related to solar energy—including passive solar equipment—is eligible for sales tax exemption in the state.

Another option for on-site energy production is the implementation of a solar water heating system. Solar water heaters can be either passive or active; passive systems are generally less expensive but not as efficient as active ones. In New Jersey, a solar water heater would need to be used in conjunction with a traditional water heating system for cloudy days and winter months.

Geothermal technologies take advantage of relatively constant underground temperatures by pumping cooler air to the surface in the summer and warmer air in the winter. One of the more common applications of geothermal technology for homeowners is ground source heat pumps (GSHPs). Properly designed and installed GSHPs can provide efficient, clean, and renewable heating and cooling for homes. The U.S. Department of Energy calculates a payback period for individual geothermal systems of five to ten years from decreased energy costs. The Resources section contains a link to the International Ground Source Heat Pump Association’s website, which maintains a database of accredited geothermal heat pump installers.
Minimize site disturbance [SS29]

For any home remodeling work, minimizing site disturbance is essential to protect the existing natural environment and prevent soil erosion, particularly in New Jersey's suburban, rural, and shore communities. Before beginning a project, consult with the contractor to develop a comprehensive plan for site protection. The NJDEP has established Erosion Control Standards for the state. Check with your New Jersey local conservation district office or the Natural Resource Conservation Service for information about strategies for soil erosion prevention (such as silt fencing, mulching, etc.) as well as any applicable laws pertaining to your project. Designate off-site parking and a controlled location for building materials when possible. Smaller sites, such as those found in urban areas, may require additional planning for proper movement of materials on and off of the site.

Carefully provide for protection of trees and vegetation. The drip line, a vertical plane going from the perimeter of the crown to the ground, contains the minimum area around a tree that should be undisturbed. However, the shallow root system found in the topsoil extends further out from the drip line, so preserving extra area beyond the drip line minimum is critical. If work requires use of heavy equipment, ask for adequate layers of straw or other material to absorb and distribute the weight to prevent soil compaction. Create tree wells for changes in grading around trunks and root systems. Consider establishing a system of incentives and penalties with the contractor for protection of existing trees and shrubs.

Planning for minimizing site disturbance conserves resources by reducing the need for new soil and plantings as well as reducing use of excavation equipment. Protecting and/or transplanting existing vegetation avoids the costs of additional future landscaping. Reducing disturbance and stress on trees and plants will reduce additional watering needs. A pre-construction low impact checklist is provided in the Resource section.

Landscape for passive heating and cooling [SS30-31/36]

Proper placement of trees and landscaping beautifies outdoor space and reduces heating and cooling costs. Taller deciduous trees on the southeast, south and southwest side of a house provide shading from the high summer sun and allow low winter sun to filter into the home. Hardy evergreen trees and shrubs placed at the northeast and northwest corners of the landscape can reduce heating costs by blocking or redirecting cold winter winds over or around the home. On west walls, incorporate trellises, arbors, and planting beds for tall annuals, which provides shading of west-facing windows where summertime heat gain is the biggest problem.

Select site-appropriate plants including native trees that may reduce watering needs once they are established. Any newly planted tree will require watering, but smaller trees will adapt much faster to site conditions. Larger trees will cost more and take longer to establish in the landscape. Evergreens (trees or large shrubs) provide greater protection from wind and noise.

It is always important to consider genetic diversity in the design to minimize potential disease and insect problems. Also see The Tree Guide at www.Arborday.org, listed in the Resources section, for growth rate and crown size information for specific tree species. Check with New Jersey arborists or your county Master Gardeners' office to choose the right plant for the particular home and lot size. It is important to balance shading with solar access, especially for systems (like solar panels) that require the sun's energy.
Distance from homes and structures are important considerations. In general, medium to large trees should be placed at least 20 feet away from the house. Trees that will be smaller at maturity can be placed closer to the house, but be mindful of the breadth of the full-grown crown of the tree to maintain both energy and aesthetic value.

Make protection of existing trees and shrubs a priority. When possible, consider transplanting rather than complete removal. If trees or large limbs require pruning, use the tree materials for firewood, mulch, or trellis construction. When transplanting, remember, that they, too, require plenty of water until they are established (generally through at least one season, depending on size).

**Maintain slope to drain away from building** [IDP13]

The soil next to the house frequently settles creating problems when water to runs toward the house rather than away from it. This creates moisture problems when you have rain or snow, and over time it will affect the durability of the foundation. Provide a minimum 6 inches of fall in finish grade over a distance of 10 feet from the building (minimum 5 percent slope) and exceed or extend this if possible. This is particularly important if there is any backfill that may induce settlement. Be sure the ground slopes away from the downspout or gutter discharge. Surface soils with low permeability next to the house (e.g., with some clay content) can help reduce direct infiltration of rainwater adjacent to the foundation. [See related strategies here and in the Outdoor Living and Landscaping section.]

**Minimize impervious surfaces** [SS32]

Stormwater runoff from impervious surfaces can cause flooding, erosion, and surface water contamination. Limiting paved surfaces and providing permeable drainage areas aids natural groundwater infiltration. Porous paving materials, vegetative swales, rain gardens, and other landscape features will improve infiltration.

An overall reduction in paved surfaces prevents runoff, allows for stormwater recharge, and mitigates the heat island effect, reducing home cooling loads. Aiding infiltration of groundwater alleviates possible moisture and mold problems that can impact indoor air quality as well.

Problems associated with water runoff are most prevalent in areas where there is a large percentage of impervious surfaces or in flood prone areas where runoff quickly collects, causing flood hazards. In those areas, or for homes with flat roofs, consider creating a roof garden to absorb stormwater on site. If a home relies on downsputs, direct them away from nonporous surfaces to allow water to infiltrate into the ground without creating runoff.

Rain gardens are depressed areas of the landscape containing various native plant species and are an effective way to reduce runoff and promote infiltration. Directing stormwater to these areas allows the plants and soil to naturally absorb and filter excess water.

The cost to replace, remove or modify existing paved areas can be significant, but it will mitigate hazards and provide various environmental benefits. See the Resources section for information regarding New Jersey’s stormwater regulations, and check with municipal offices for any specific policies.

**Tips** [IDP13]

Obtain a straight 2x4 that is 10 feet long and use a carpenter’s level to ensure the ground slopes away from the house at least 6 inches over 10 feet.

**NJ Bio-Region** [IDP13]

Different soils have different absorption properties. Where only pervious soils are available for backfill, the slope of grade away from the perimeter of the foundation should be increased or an impervious “skirt” of 6 mil polyethylene may be placed about 12” below grade.

**Tips** [SS32]

Some porous paving systems may not be appropriate for New Jersey’s climate. See: “Standard for Pervious Paving Systems” from the NJDEP Best Practices Manual in the Resources section, and check with an expert if you are unsure about the compatibility of a particular product.
Landscape to minimize heat island effects

**Benefits**
- **Energy Savings:**
- **Water Savings:**
- **Resource Conservation:**
- **Air Quality:**
- **Feasibility**
- **Initial Cost:**
- **Difficulty Level:**

The heat island effect occurs in densely developed areas. It happens where high areas of built surfaces like brick, concrete, asphalt and stone, absorb short-wave solar radiation during the day. These surfaces store heat which is emitted later as long-wave radiation, resulting in increased temperatures. Areas with less vegetation will also have less of the cooling effect created by evaporation of water from soil and leaves, exacerbating this localized warming.

The higher temperature in heat islands leads to greater air conditioning use, which increases overall energy use. As power plants burn more fossil fuel to meet the increased demand, pollution levels also rise. The rising pollution levels, exacerbated by high temperature, create smog which can create respiratory health problems and additional greenhouse gases are also emitted.

Minimize heat islands by planting native trees and shrubs to provide shade and reduce paved surfaces. Properly placed trees and vegetation can reduce energy used for heating and cooling by up to 25 percent.

During remodeling, minimize damage to existing vegetation and transplant any trees or shrubs that must be removed. Use water as a landscape element to reduce the effects of heat islands. On flat roof homes, garages, and sheds, consider installing a vegetated or “green roof” to replace heat-absorbing surfaces with plants, shrubs, and small trees that cool the air through evapotranspiration.

If an existing roof is steeper than 12 degrees or the supporting structure is not strong enough to support a green roof, consider providing a reflective roof to minimize the heat island effect.

Plan for erosion control

**Benefits**
- **Energy Savings:**
- **Water Savings:**
- **Resource Conservation:**
- **Air Quality:**
- **Feasibility**
- **Initial Cost:**
- **Difficulty Level:**

During construction, take steps necessary to prevent soil erosion. Up to 1.7 tons of wood waste is generated during the construction of a 2,000 sq. ft. home. Scrap lumber, pallets, sawdust, tree stumps, branches, and twigs that cannot be used for firewood or other use can be chipped or ground on-site and used as mulch to protect against soil erosion. Pack ground wood chips into woven ‘socks’ and place them on the edges of the construction site or around sewer drains to control runoff and prevent soil loss from a site.

After the site has been rough graded to control erosion, wood chip mulch may also be spread uniformly on the site as a temporary cover to reduce soil loss and allow vehicular and foot traffic over the area. When used in this way, the wood chips form a blanket over the soil to moderate its temperature, conserve moisture and provide an environment conducive to seed germination.

Untreated/unpainted dimensional lumber and engineered lumber such as Oriented Strand Board (OSB), plywood and particleboard can all be mulched. Apply mulch uniformly at a rate of 6 to 9 tons per acre to achieve a minimum of 80 percent ground cover. This level of application creates a layer of wood chips or wood bark to approximately one inch thick.
To save money, test for radon before beginning to remodel or convert an unfinished basement area into living space as it is more cost effective to do the mitigation as part of the renovation. A homeowner can conduct a radon test or hire a New Jersey certified radon measurement company to perform the testing. Some certified radon measurement companies sell test kits through mail order and test kits are often available in hardware stores or from local health departments. A single short-term test of 2-7 days in length can be used to indicate the radon level in your home. A long-term test of 3-12 months will provide your best estimate of average exposure over time, since radon levels fluctuate daily and by season. If mitigation is required, a certified mitigation company should be consulted.

The most common type of radon mitigation system is the sub-slab depressurization system. It is comprised of a vent pipe system and fan that pulls radon from beneath the house and vents it to the outside. The exhaust system runs 24/7 and does not require major changes to the home. The piping can run either in the house with the fan generally located in the attic or outside with the fan on the side of the house. The radon is vented through the pipe to the outside, where it is quickly diluted. Cracks and openings in the foundation are sealed.

Homes undergoing green remodeling, in which new additions are part of the project, can include Radon Resistant New Construction techniques. These techniques include a gas permeable layer (e.g., 4-inch layer of gravel) beneath the slab to allow the soil gas to move freely underneath the house, plastic sheeting on top of the gravel to prevent the soil gas from entering the house, and a PVC pipe that runs through the house and roof to vent radon above the house. After testing, if the home has elevated radon levels, an electrical venting fan can easily be installed to activate the system at a reduced cost compared to a complete mitigation system.

The Department of Community Affairs requires all new construction of Groups E and R buildings in tier one areas (as defined by the New Jersey radon potential map) to meet the Radon Hazard Subcode of the Uniform Construction Code. This section further states that full compliance with the construction techniques is not required for additions in tier one areas; however, those construction techniques that are feasible are to be incorporated. These features can be incorporated voluntarily in tier two and tier three areas.

For more information and assistance in finding a certified radon professional, homeowners can contact the New Jersey Department of Environmental Protection’s Radon Program at (800 648-0394 or visit www.njradon.org.

### Insulate floor slab and foundation walls

Often basements are cold and damp, but properly insulated foundation walls and floor slabs can reduce heating and cooling costs and result in more comfortable below-grade rooms. It can also help to prevent problems with moisture, insects, and radon in the home.

Use the U.S. Department of Energy’s Zip-Code Insulation Program to determine how much insulation to add and where to achieve the recommended insulation levels for maximum energy efficiency. See: www.ornl.gov/~roofs/Zip/ZipHome.html

If the exterior surface of the existing foundation walls can be accessed, that generally is the best location for added insulation. When possible, insulate exterior foundation walls with rigid
insulation board and water-proof coating. In most cases, it is not possible to access the outside of the walls, so insulation must be added to the interior walls.

When adding insulation to existing foundation walls consider using loose-fill or sprayed foam insulation. These insulation materials can be added to interior walls without disturbing finished areas of the home, and then can be covered with non-paper-faced gypsum board. A finished basement space may also incorporate a wall system built in layers, insulated, and finished with non-toxic materials. Wall panel units incorporating Oriented Strand Board (OSB) can be applied using non-toxic glues. Another approach uses ceramic-based thermal paints that adhere to stucco and concrete and provide moisture, vapor and heat-loss controls without additional insulation layers.

Creating an insulation layer and a vapor barrier between the concrete slab and the ground beneath is the best approach for basement insulation. It’s important to insulate under the slab (which may not be feasible for existing basements), but insulating around the sides of the slab is equally important. Slabs may be insulated at the perimeter on the exterior side with borate-treated foam board or rigid glass fiber insulation. Slab perimeters may be insulated on the interior side as well. This approach requires rigid insulation placed between the slab and the foundation wall, and under the slab, as required by local code.

For new additions, consider materials such as insulated concrete forms (ICFs), insulated pre-cast concrete wall systems and structural insulated panels (SIPs) to provide structural support with built-in insulation. SIPs are made from a thick layer of foam (polystyrene or polyurethane) sandwiched between two layers of Oriented Strand Board (OSB), plywood, or fiber-cement.

Provide moisture control at foundation

Basements present extra moisture management challenges because of their proximity to the water table; foundations are one of the leading sources for moisture in the home. Moisture can enter the foundation through concrete slab floors and foundation walls. The best way to deal with moisture at the foundation is through proper foundation design, quality construction, and proper exterior drainage. Best practices in foundation design for moisture control include tamped, crushed stone under a foundation slab, a layer of durable polyethylene (protected from abrasion with insulation or sand), a capillary break between the footing and foundation walls, a damp proofing layer on the foundation exterior, and a drainage layer on the outside of the foundation wall, including geofabric to keep silt out of the drainage layer and drainage pipe.

Utilize Integrated Pest Management

The foundation is the primary entry point for insects, so follow Integrated Pest Management (IPM) best practices and keep untreated wood and vegetation at least a foot away from the soil line and foundation walls.

IPM best practices minimize environmental impacts by using eco-friendly methods to control pests. IPM’s prevention, monitoring, and control techniques offer an alternative to chemical pesticides. IPM techniques enhance sustainability of vital natural systems, promote insect and disease resistant lawns, trees and shrubs, and protect beneficial insects. IPM reduces threats to wildlife and water quality from chemicals that would otherwise reach our drinking and recreational water resources.
Use biobased form-release agents  [MR115]  

Standard form-release agents protect concrete surfaces from stains and help with mold control; green versions are made with biodegradable vegetable oils. Form-releasers help remove concrete formwork from hardened concrete footings and walls after concrete has set. Wood or metal foundation forms often are coated with petroleum-based oil so they won’t stick to the concrete. However, the oil from these conventional petroleum-based products remains on the concrete even after the forms are removed – where it can seep into the ground around the foundation and contribute to indoor air quality problems. In general, products such as water-based form-release compounds using soy or other biologically-derived oils are biodegradable and are less harmful to indoor air quality.

Another option to removable concrete forms is permanent Insulating Concrete Forms (ICFs) that add both thermal and waste reduction benefits to the project when used as walls for a foundation or addition.

Use fly ash in concrete  [MR114]  

Before there was portland cement, the Romans created concrete structures using lime and a volcanic ash that reacted with the lime and hardened the concrete. Coal fly ash – the particulate matter collected by pollution-control equipment from the smokestacks of coal-burning power plants – has a similar strengthening effect because of its silica and alumina content.

Fly ash increases the durability of concrete and can also be used to shrink its environmental footprint by requiring less portland cement in the mix as producing 1 ton of portland cement emits 1 ton of carbon dioxide. Replacing 25 percent of cement with fly ash is a common practice, and up to a 50 percent substitution is acceptable for certain applications. However, concrete with high concentrations of fly ash must be tested before each application because the chemistry of the material varies more than that of portland cement; if too much fly ash is used, the concrete’s freeze-thaw resistance is reduced. Mixes with higher levels of fly ash must also be cured differently, as they tend to cure more slowly. Specify the use of fly ash in concrete in the construction contract.

Conduct a Home Performance Audit and diagnostic tests  [IPD2/EA51-54]  

A Home Performance Audit identifies energy upgrades for cost savings. Diagnostic tests examine the whole house and look at the interactions between all systems in a home: air leakage, insulation, combustion appliances, heating and cooling systems, and ventilation. Several free online energy audit tools are available for homeowners. The NJ Office of Clean Energy’s Home Energy Analysis Tool offers specific recommendations based on the age of the home; average energy usage,
Certified professionals can conduct a more comprehensive Home Performance Audit. This often includes a combination of visual inspections and diagnostics tests to identify opportunities to repair or upgrade aspects of the building envelope or mechanical systems. The following strategies are common elements of a more comprehensive Home Performance Audit:

- **Blower Door Test** – Blower door tests help determine a home’s airtightness. Proper airtightness is important for reducing energy use and drafts due to air leaks, avoiding moisture problems, and regulating indoor air quality. It is important that auditors use a calibrated blower door, which allows them to test airtightness before and after recommended changes have been implemented, and to verify that the work completed solved the problems.

- **Thermographic inspections** - Thermographic inspections or infrared scanning uses specially designed infrared video or still cameras to make images (called thermograms) that show surface heat variations. Thermograms help determine whether and where a home needs insulation. Because wet insulation conducts heat faster than dry insulation, thermographic scans can also detect roof leaks and other moisture problems.

- **Thermal Bypass Inspection (TBI)** – The Energy Star® Thermal Bypass Inspection (TBI), and a corresponding checklist, is designed to check for missing or incorrectly installed insulation and sealing of penetrations and air gaps. It is most commonly performed for new construction and major renovations. Reducing thermal bypass, or the movement of heat around or through insulation, is important as they can lead to comfort issues as well as higher utility bills. For more information, see the Energy Star® Thermal Bypass Checklist: [www.energystar.gov/index.cfm?c=bldrs_lenders_raters.thermal_bypass_checklist](http://www.energystar.gov/index.cfm?c=bldrs_lenders_raters.thermal_bypass_checklist)

The NJ Office of Clean Energy Home Performance with Energy Star Program provides reduced fee home energy audits and a listing of certified energy auditors on its website.

### Minimize wood use with advanced framing

Use advanced framing techniques to reduce the amount of unnecessary wood material used in a major addition project and therefore lower costs. Switch to 24-inch studs and roof trusses or rafters, switch from a double to a single top plate (and align roof trusses or rafters with wall studs), eliminate unnecessary studs, and replace solid-wood headers above windows and doors with engineered (and insulated) headers. Advanced framing also improves energy efficiency by replacing lumber with insulation material.

The type of wood used in advanced framing contributes to resource conservation. Insulated wood products such as Oriented Strand Board (OSB), is typically made from secondary lumber and scrap wood, so it relies less on ecologically valued old growth timber. Another material, Structural Insulated Panels (SIPs), made with a rigid insulated foam sandwiched between layers of OSB, replaces structural framing altogether. Its built-in insulation provides a tight building envelope. Consider SIPs constructed with low- or no-formaldehyde glue for further reduction of air impacts.
Install or upgrade insulation

Insulation slows down the heat flow through a home’s building envelope - the walls, attic, roof and basement. In the winter, insulation slows heat loss and helps prevent moisture buildup. During summer months, it reduces heat gain and helps keep a home cool.

Insulation is rated according to its R-Value, or its ability to resist heat flow, with a high R-Value being a greater resistance. Adding insulation with a higher R-Value can cut heating and cooling costs anywhere from 15 to 45 percent, depending on factors such as the original amount of insulation in the home, house size, air leaks and personal energy use and living habits.

Certified energy auditors conduct an insulation check as part of a comprehensive home performance audit. They can determine the R-Value of the home’s current insulation and measure air leakage. They then can recommend where air sealing and insulation should be added.

Thorough air sealing should be done before insulating. Insulation alone does not protect against air leakage; moist air can damage the insulation and reduce its effectiveness. Adding insulation before air sealing may make some air leaks difficult to access. Avoid thermal bridging by installing a layer of continuous insulating sheathing over frames or joists.

The general rule of thumb is to install insulation on any surface separating a heated space from an unheated space; walls, ceilings, attics, floors and ducts should be well-insulated. One of the best places to begin installing or upgrading insulation is in the attic as a significant amount of heat can be transferred through the roof. Installing attic insulation is also a relatively easy job for do-it-yourselfers.

There are four basic types of insulation:

- **Batts** and blankets—Batts and blankets are made from mineral fibers, such as fiberglass and rock wool and typically have a value of R-3 per inch. They are available in widths suited to standard spacings of wall studs and attic or floor joists; 2x4 walls can hold R-13 or R-15 batts and 2x6 walls can have R-19 or R-21 products. Use this type of insulation below floors, above ceilings, and within walls. Batts and blankets can be installed by homeowners or professionals.

- **Loose-fill insulation**—Loose-fill insulation is often made from fiberglass, rock wool, or cellulose in the form of loose fibers or fiber pellets and typically has a value of R-3 to R-4 per inch. This type of insulation works best in places where it is difficult to install other types of insulation such as building cavities and attics. Loose-fill insulation is usually blown in by professional installers.

- **Rigid insulation board**—Rigid insulation board is often made from fiberglass, polystyrene, or polyurethane and typically has a value of R-4 to R-8 per inch. Use this type of insulation on basement walls and as perimeter insulation at concrete slab edges, and in cathedral ceilings. For interior applications it must be covered with 1/2-inch gypsum board or other building-code approved material for fire safety. For exterior applications, cover with weather-proof facing.

- **Spray foam**—Spray foam insulation comes in two forms: open-cell and closed-cell. The closed-cell foams typically have a higher R-value (R-7 to R-8 per inch) than open-cell foam (R-5.6 to R-8 per inch). Most foam insulation products have a higher R-value per inch than fiberglass batt insulation.

Vermiculite Insulation was used in attics until it was discovered that vermiculite ores from some sources have naturally occurring asbestos in trace amounts. This type of insulation is only a health concern when someone comes into contact with it; while it is contained, it is not determined to be a health risk. If a remodeling or renovation project involves removal of this type of insulation, certified professionals will be needed to safely remove or contain the material. For more information, see EPA website: www.EPA.gov/asbestos/pubs/verm.html.

Federal tax credits may be available for added insulation to walls, ceilings, or other part of the building envelope. See the Tax Incentive Assistance Project: www.energystar.gov/savemoney/guide/summary

Federal tax credits may be available for added insulation to walls, ceilings, or other part of the building envelope. See the Tax Incentive Assistance Project: www.energystar.gov/savemoney/guide/summary

In colder climates, adding extra insulation is more cost effective than installing a radiant barrier.

Insulation in older homes will have settled and at best be dusty or dirty so new attic insulation is typically installed on top of old insulation.

Vermiculite Insulation was used in attics until it was discovered that vermiculite ores from some sources have naturally occurring asbestos in trace amounts. This type of insulation is only a health concern when someone comes into contact with it; while it is contained, it is not determined to be a health risk. If a remodeling or renovation project involves removal of this type of insulation, certified professionals will be needed to safely remove or contain the material. For more information, see EPA website: www.EPA.gov/asbestos/pubs/verm.html.
Install a durable wall cladding [MR119]

A durable wall cladding should be part of the home’s moisture management strategy. Proper installation of cladding requires a layered approach with an air space or rainscreen behind the siding so this area can dry out while also fully sealing the building envelope. Newer versions of house-wrap have textured surfaces that create a drainage plane to move water more readily behind the cladding and out to the wall assembly.

Siding properly installed over a rainscreen requires less frequent painting or staining than when installed directly over sheathing, reducing the need for refinishing. Factory pre-primed claddings are also highly efficient. Noncombustible siding, such as fiber cement, adds fire protection and is often required by building codes. This must be layered with fire-resistant screening in the air space behind the cladding to be effective.

Air seal to reduce infiltration [IDP55]

Air infiltration or leakage may contribute to as much as 30 percent of a home’s heating and cooling costs. The most common sources of air infiltration are the attic, crawl space, or basement, and around windows, doors, and chimneys. Other sources include plumbing chases, electrical outlets, attic accesses, dropped ceilings and leaky ducts.

Reduce air leakage as much as possible before adding insulation and provide controlled ventilation as needed. First, identify air leaks in the home (see Conduct a Home Performance Audit and diagnostic tests [IDP2, EA51-EA54]). A good rule of thumb is to seal the high and low air leaks first. Start by plugging holes and leaks in the attic and basement, then move to the exterior wall, and look for smaller leaks around doors, windows and electrical switches and outlets. Use caulk to seal openings up to ¼ inch such as cracks and gaps between window frames and siding. For larger gaps, add a backing material before caulking or use a spray foam sealant. After all the larger air leaks have been sealed, weather-strip doors and windows.

Include capillary break [IDP22]

Rain water infiltration is the largest source of material deterioration in buildings. Capillary breaks maximize protection using materials such as sill sealer or gaskets. Capillary breaks are placed at the critical junction between a wet footing and a dry wall for moisture control at the foundation. They prevent capillary action of moisture through small interconnected spaces or “wicking” in the building. A sill sealer or gasket installed between all concrete and framing on exterior foundation walls serves as a capillary break. Airspace serves as a capillary break when it prevents water from saturating the drainage plane. To prevent moisture migration between the concrete foundation and the floor structure above, a capillary break should be installed between the top of the concrete and the sill plate to isolate the wood frame from any source of moisture and prevent rot. A capillary break installed between the footing and the concrete wall limits ground water absorption through the footing.
While the capillary break is important between all bottom plates, concrete foundation walls, or floors, under some conditions it can be expensive to implement. This is especially true in older homes, where interior and exterior wall heights may not line up. Weigh the full costs and benefits before deciding to implement this strategy.

Provide moisture management strategies [IDP24]

A dry house is a more durable house. Not properly managing moisture effects both the durability of the structure of the building and indoor air quality, as mold can quickly reach toxic levels.

The building envelope plays a key role in the total performance of the building, so most moisture management strategies focus here. Several strategies keep the building envelope drier. Roof overhangs and overall sealing of any roof and wall penetrations are major examples. Incorporate a house-wrap or weather barrier when replacing the exterior cladding. Create a drainage plane, such as house-wrap with texture, placed under siding to allow hidden wet spaces to dry more quickly.

The integrity of the building envelope can be challenged by moisture in any state: 1) liquid, in the form of rainwater penetration, 2) solid, such as ice and snow, and 3) vapor, such as relative humidity. If these conditions are not managed properly, they can lead to premature decay of the home. [See additional window, wall and foundation strategies in this section to understand how to best manage moisture.]

Follow standards for mechanical design [EA63]

The Air Conditioning Contractors of America (ACCA) developed standards to size heating, ventilating and air conditioning systems (HVACs) to assure maximum comfort and energy efficiency. The ACCA also provides software that calculates heating and cooling loads. Use these calculations both before and after HVAC installation to assure effectiveness. Request load calculations from contractors to validate the overall size and design proposed. Addressing building envelope issues at the design phase can reduce the load and resulting size requirement of the home’s HVAC systems.

The ACCA Manual J - Residential Load Calculation accurately estimates heating and air conditioning loads. Manual S – Residential Heating and Cooling Equipment Selection recommend optimal heating and cooling equipment to meet loads as identified from Manual J results. Use the Manual S calculation to assure proper sizing based on the square footage and the home’s heat loss during cold weather and heat gains during warm weather. Over-sizing and improper design are major issues in HVAC installation and design. Over-sizing can compound the cause of indoor climate issues such as inconsistent temperatures from one room to another. Calibration of the sensible (or dry) cooling load and the latent (or wet) cooling load assures interactions with windows or people will be accounted for in the design.

Manual D – Residential Duct Systems provides tools for proper duct sizing and is used in conjunction with Manual J and S calculations. Correct sizing is essential to maximizing HVAC energy efficiency. A system that is too big used with a smaller duct system creates improper air flow and raises the utility bill. Proper duct design assures even air flow to each conditioned space within the home. Similar to the issues faced with an improperly or oversized HVAC unit, improper duct system design can lead to increased energy bills and a lack of comfort in the home due to an imbalance of heating or cooling in the conditioned spaces. Additional duct design attributes
include well-insulated and sealed ducts, which are best placed within conditioned space and with a minimum number of turns. Placement of the duct system is also essential to assure energy efficiency, promote proper functioning of the entire unit, and reduce future maintenance requirements.

Provide controls and zoning for HVAC

The heating, ventilating and air conditioning (HVAC) system distributes air through the home via the ducting system. Assuring proper distribution across defined zones or areas of the home is another key design element and should be considered in conjunction with sizing to assure an efficient system. This is especially true in determining optimal load calculations and appropriate air flow for each room. Zoning more effectively directs heating and cooling from a single HVAC system to multiple areas of the home than multiple HVAC units and avoids the added expense that comes with them.

Proper zoning controls optimal comfort and efficiency. A zone controller connects multiple thermostats to the single HVAC system and allows for cooling customization, such as focusing the cooler air in occupied spaces at optimal times. Zoning increases overall thermal comfort of a home and is particularly useful in larger houses that are poorly conditioned, such as single-zone two-story houses with a generally warmer second floor.

Select high-efficiency HVAC equipment

Heating is the largest energy expense in most homes, accounting for 35-50 percent of annual energy bills in northern New Jersey climates. Save money by reducing heating energy usage while also reducing the home’s contribution to environmental problems by upgrading to Energy Star®-rated heating equipment as determined by the Annual Fuel Utilization Efficiency (AFUE) rating for oil and gas furnaces and boilers (and other measures as applicable to heat pumps). Energy Star® rebates apply for Energy Star®-rated equipment.

The American Council for an Energy-efficient Economy cites several considerations for assessing when it is time to replace the furnace. In particular, gas furnaces or boilers or those that are older than 20 years are good candidates for replacement with a high-efficiency model with the guidance of an Energy Star® certified heating contractor and heat-load calculations that the contractor provides. If it is time to replace the furnace, installing a ground-source heat pump could be an option depending on the extent of the remodeling effort (see the Ridgewood historical remodel for a case study installation of a heat pump).

The efficiency of central air conditioning systems is rated by its Seasonal Energy Efficiency Ratio (SEER). SEER ratings range from 14 to 23; a higher SEER rating means a more efficient unit. Energy Star®-qualified central air conditioners have a SEER rating of greater than 14 and are significantly more efficient than standard models. Newer units in general contain significant technological advances to increase efficiency. The minimum Energy Efficiency Ratio (EER) for Energy Star®-models is greater than 12 for split systems, and greater than 11.0 for single-package models. Higher efficiency units often cost more initially, but save on operating costs over their lifetime. However, it should be noted that a high-energy-efficient unit must also be designed, installed and maintained properly to reap efficiency benefits [see EA63].

An effective pleated filter also contributes to savings on heating/cooling and helps prevent the introduction of pollutants into the living space. Radial pleated filter designs such as a ‘MERV 8’
provide optimal dust holding capacity, especially as compared with standard rigid fiberglass filters that provide little resistance against dust or bio-contaminates.

A highly-efficient unit must be designed, installed, and maintained properly to reap efficiency benefits. Keeping your efficient filter clean is an essential component of HVAC maintenance.

Install programmable thermostats [EA67]

Programmable thermostats save energy and money by allowing homeowners to set temperatures based on occupancy and to schedule setting changes. This uses heating and cooling only when needed. Programmable thermostats are especially useful if the house is empty during the work week and only fully occupied on weekends. Pre-programming and proper use of a programmable thermostat saves energy costs by minimizing heating or cooling of an empty house.

Conduct duct tightness test [EA68]

Similar to a pressure test of a plumbing system, a Duct Blaster Test gauges the tightness of the ductwork. It uses a fan combined with a pressure gauge to pressurize the duct system and measure air leakage of the ductwork. The test is often performed along with a Blower Door Test as part of a Home Performance Audit to find leaks. It should be performed before and after related work to properly identify and target areas for action and to assure resolution of desired upgrades to ensure energy and operating cost savings.

Maintain HVAC systems [EA69]

Heating, Ventilating, and Air Conditioning (HVAC) systems can be commissioned or tested to ensure refrigerant charge, airtight ducts, proper room-by-room pressure and proper airflow.

HVAC systems must be properly balanced to ensure even distribution of air and needs to be inspected, tested, and tuned up after installation. Zoning and other controls should also be tested to make sure they are functioning properly. To confirm functioning, have it commissioned. Commissioning provides documented confirmation that the HVAC systems are working as intended.

Commissioning systematically investigates, analyzes, and optimizes the performance of HVAC systems to improve their operation; maintenance ensures continued performance over time. Regular maintenance ensures that the energy efficiency upgrades remain at optimal levels as designed and are meets the homeowner’s current needs.

To protect an investment in an HVAC upgrade and assure its efficiency over time, HVAC equipment should be tuned up annually and filters should be cleaned or be replaced on a regular basis. Energy Star recommends tending to filters every 30 days during peak heating or cooling season. The wrong amount of refrigerant in air conditioners can also impact the functioning of the cooling unit. Proper maintenance extends the life of the HVAC system, extending the resource value of the system.

Caution [EA68]
If replacing heating or cooling units, assure proper disposal of the older units; make sure your contract defines the disposal process.

Tips [EA68]
A well-sealed vapor barrier may need to be installed on the outside of the insulation on cooling ducts to prevent moisture buildup.

Building Age [EA68]
Historically, only supply ducts were sealed, ignoring return ducts and plenums. Older homes will likely have leaks on the return side.

Caution [EA68]
If ducts don’t work properly, they can cause build up of carbon monoxide (CO). If you have a fuel-burning furnace, stove or other appliance, or an attached garage, install a CO monitor to alert you if any of these situations create harmful CO levels. www.eere.energy.gov/consumer/tips/ducts.html

Tips [EA69]
Hire a technician trained to use advanced diagnostic tools and procedures to verify installation and operational requirements. For more information, see www.energystar.gov/ia/home_improvement/PHEE_InstallationAC_final.pdf

Building Age [EA69]
Commissioning is especially important in older homes to achieve optimal performance without having to replace equipment. Newer HVAC systems use high grade filters; these must be changed as scheduled to ensure the optimal functioning of the filter.
Sealing duct leaks is an essential aspect of an HVAC retrofit but is a challenge depending on accessibility of ductwork. Make sure the certified contractor addresses ductwork that is in unconditioned spaces, overall effectiveness, and costs before proceeding with work.

**Caution**

Improperly balanced systems can depressurize the house, allowing radon and other hazardous soil gases to enter the home.

The commissioning process should check for refrigerant leaks that can emit refrigerant gasses into the air.

**NJ Bio-Region**

A correctly sized and sealed HVAC system can be used to control mold related problems by removing humidity from the indoor air.

**Building Age**

Sealing duct leaks is an essential aspect of an HVAC retrofit but is a challenge depending on accessibility of ductwork. Make sure the certified contractor addresses ductwork that is in unconditioned spaces, overall effectiveness, and costs before proceeding with work.

**Caution**

Pressure imbalances due to duct leakage can force moisture laden air into building envelopes and lead to moisture problems.

**Tips**

If you must clean the ductwork, check references and licenses and make sure the provider is a certified member of the NADCA. Air duct cleaning companies must meet requirements to become a NADCA Member including having certified Air System Cleaning Specialists (ASCS) on staff.

**NJ Bio-Region**

Higher humidity can cause mold growth in the ducts, requiring more frequent maintenance and cleaning.

**Building Age**

Inspect older duct systems before cleaning to be sure they do not have asbestos-containing materials.

To assure regular maintenance, homeowners should consider setting up an HVAC maintenance contract for “tune-up” of your HVAC system before heating and cooling seasons to protect performance. A maintenance contract can pay for itself in energy savings and ensures that your HVAC contractor will schedule tune-ups even if you forget.

**Seal and insulate HVAC system**

A house can lose over 30 percent of its heating and cooling capacity from improperly sealed ducts, especially if the ducts are located in unconditioned spaces. In the winter, hot air leaks into unconditioned spaces and causes the furnace to work harder. In the summer, hot attic air can leak in and increase the load on the air conditioner. A perfectly sealed operative duct system would have the same amount of air entering the return grille and leaving the supply registers, creating neutral air pressure. In contrast, leaky supply ducts create negative pressure that pulls outside air into the building. On the return side, leaks cause a suction that pulls air into the ducts, forcing more air into the home and creating a positive pressure that also overtaxes the HVAC system.

Seal all ducting with low-VOC duct mastic. The Energy Star® Thermal By Pass Checklist recommends the use of mastic, not tape, to seal ducts. Results have shown that using tape to seal ducts is ineffective as tape often frays and curls away degrading the seal. If any ductwork is in less desirable condition, or in uninsulated areas, additional insulation most likely will be required. A qualified professional can help insulate and repair ducts.

**Make sure ductwork is clean**

Duct cleaning refers to the cleaning of heating and cooling system components in forced air systems, including the supply and return-air ducts, registers, grilles, diffusers, heat exchangers, heating and cooling coils, drain pans, fan motor, fan housing, and the air handling unit. While clean ducts help maintain healthy indoor air quality, unless done properly, cleaning ducts can cause more indoor air problems.

If a visual inspect reveals infestation, mold or extreme debris problems, duct cleaning may be necessary. If so, be sure the service provider cleans all components of the system to avoid any recontamination that may require more serious cleaning needs. Be sure the service provider is qualified by the National Air Duct Cleaners Association (NADCA). A certified service provider uses specialized tools to dislodge dirt and other debris in ducts and vacuums them out with a high-powered vacuum cleaner. Different types of ducts require different cleaning methods; sheet metal ducts with external insulation are the easiest to clean. A Duct Blaster Test should also be performed when cleaning ducts to gauge the tightness of the ductwork. Finally, be sure to cover duct registers and openings during renovation or remodeling.
Use ceiling fans for natural ventilation

**Benefits**
- **Energy Savings:**
- **Water Savings:** N/A
- **Initial Cost:** $0

**Feasibility**
- **Resource Conservation:**
- **Air Quality:**
- **Difficulty Level:** TT

Use ceiling fans in conjunction with an air conditioning system in occupied rooms; people can tolerate higher temperatures when air is in motion. This reduces air conditioning use, saving money and electricity. In the summer, run ceiling fans in a counterclockwise motion; ceiling fans also can be used in the winter in a clockwise motion at low speeds to bring warm air back down into the occupied space.

Also consider a whole house fan in the attic to avoid air conditioner usage and expense. Generally a whole house fan is used at night and turned off during the day. It moves cooler nighttime air into the house through open windows and exhausts warm air through the attic.

Another way to cool the home is with transoms in window and door designs. Designing for convection directs cool air to enter the home on the lower floors (such as through the basement) and expels warm air through upstairs windows.

Strategic location of plants and landscaping can cool the air before it enters the home. Finally, awnings and blinds provide additional passive cooling options.

**Insulate water heater**

**Benefits**
- **Energy Savings:**
- **Water Savings:** N/A
- **Initial Cost:** $0

**Feasibility**
- **Resource Conservation:**
- **Air Quality:**
- **Difficulty Level:** T

New water heaters have added interior layers of insulation that improve their energy consumption. Older water heaters are the third largest energy expense in the home, accounting for about 13 percent of the utility bill. Insulate free-standing water heater storage units for quick and inexpensive improvements in energy efficiency. Heat is lost because the temperature inside a water heater is significantly higher than the temperature of the room, especially when the water heater’s location is unconditioned. Water heater blankets and kits are available from local hardware stores and weatherization supply companies.

**Insulate hot water pipes**

**Benefits**
- **Energy Savings:**
- **Water Savings:**
- **Initial Cost:** $0

**Feasibility**
- **Resource Conservation:**
- **Air Quality:**
- **Difficulty Level:** T

Hot water pipes usually run through unheated areas of the home, so insulating them is important to prevent heat loss and help the water heater run efficiently. Insulated hot water pipes reduce water usage by increasing the amount of time that hot water stays hot thereby reducing the need to run tepid water through the faucet. Requiring less energy to heat water also reduces water heating bills.

Insulating hot water pipes on accessible pipes is an easy task. Pre-formed foam pipe insulation sleeves (available at local hardware stores) can be cut to fit snugly and snap in place on the pipes. Use a durable pipe insulation material that can withstand high temperatures over time. Cover slits and joints with vinyl duct tape to provide additional insulation.
Utilize solar water heating [EA101]

Solar water heating is cited as the most cost-effective renewable energy system for residential applications. Payback periods related to solar water heating differ depending on the cost of energy for heating water. In areas where electricity is used for water heating, the payback periods are shorter than for areas that use natural gas for water heating. Installing a solar water heater is a proven solution to reducing the home’s carbon footprint. Conventional electric water heaters produce about eight tons of CO₂ annually and gas water heaters about two tons of CO₂ annually. Solar water heating can be used for domestic hot water, pool heating, and space heating needs and is in use by over a million homes in the United States. There are many types of solar water heaters. Evacuated tube solar hot water system can provide 90 percent–100 percent of domestic hot water needs. Appropriate design and climate considerations are key in the consideration of any solar project. Care must be taken to guard against freezing of the collector and piping, and evacuated tubes for solar hot water can overheat and break if the power went out on a sunny day.

Plan for future wiring and cabling needs [MR121]

Cabling for electrical equipment is an important consideration in any 21st-century home, but especially in any space that could be used as a home office. Living rooms also have increased cabling needs if home has more sophisticated audio and visual systems. Recent changes from standard phone lines, to ethernet, to T-1 and fiber-optic created a need for enhanced electrical, communications and data cabling. It is possible that wireless technology will obviate the need for communications, and data cabling altogether, but to plan for the unknown and minimize the likelihood of expensive cabling upgrades in the future, provide either wiring conduits through which new cables can be run or surface-mounted wiring raceways. In addition to planning for adaptability, provide plenty of electrical receptacles and communications ports to give flexibility within the spaces.

Provide daylighting [EA83]

Sunlight is a natural way to reduce energy use during the daytime hours. Homes that only require artificial lighting at night and on darker days save more electricity and are more aesthetically pleasing than ones that do not.

Windows and skylights are obvious sources of daylight, but balance daylight access with appropriate glazing and shading techniques. Poorly designed window or skylight layouts can increase summer cooling loads significantly. Awnings, louvers, and shutters can block direct sunlight and allow indirect sunlight into the building. Conversely, a well-designed scheme reduces heating loads significantly in the colder months. In the northern hemisphere, south facing windows receive the most sunlight over the course of the day. For these windows, properly sized overhangs will shade the window from direct summer heat but will allow the lower winter sunlight to filter through.
An alternative to window skylights is solar tubes. The flexible cylinders of the solar tubes draw sunlight from the roof into a ceiling fixture resembling a standard lighting fixture. They are useful in smaller interior rooms without space for a traditional skylight, such as a bathroom. Translucent panel skylight systems are another means of allowing sunlight in without producing glare and minimizing heat transfer.

Provide appropriate lighting [EA84]

Lighting consumes almost 15 percent of a household’s electricity use. Provide an appropriate mix of color-correct ambient and task lighting to improve both the quality and quantity of lighting used in the home.

Two ways of determining which lighting is appropriate for a particular use are its color temperature and its Color Rendering Index (CRI).

Color temperature defines the color and warmth or coolness of a light source. Color temperature is measured in degrees Kelvin (K). High Kelvin temperatures (3600–5500 K) are considered “cool” and low color temperatures (2700–3000 K) are considered “warm.” Task lighting calls for cool light that produces a higher contrast than warm light and is better for visual tasks. Warm light is recommended for living spaces. A color temperature of 2700–3600 K is generally recommended for most indoor general and task lighting applications.

The Color Rendering Index (CRI) is a 1-100 scale that measures how colors appear under different light sources. A light source with a CRI of 80 or higher is considered acceptable for most indoor residential applications.

Install energy-efficient lighting [EA85]

Traditional incandescent bulbs will be phased out by 2012. The technological improvements in compact fluorescent lighting (CFLs) over the past decade have made for a smooth transition. CFLs are inexpensive, last ten times as long as traditional bulbs, and use a fraction of the electricity. They also fit into standard light fixtures, allowing for their widespread use with minimal up-front cost.

Light-emitting diodes (LEDs), currently used in a variety of applications, potentially could find their way into more traditional lighting applications. Highly efficient, durable, and non-toxic, LEDs currently cost too much to warrant their widespread use. However, rapid advances in LED technology continue to push LED lighting to more practical uses.

Wherever possible, replace incandescent bulbs with greener alternatives. It is a simple and affordable way to significantly reduce home energy use.
Provide appropriate indoor lighting controls [EA90]

<table>

</tr>
</tbody>
</table>

Lighting represents about 15 percent of household electricity usage and about 10 percent of household energy expenses. Newer lighting technologies, extensively used in commercial buildings, are now available for home use. These technologies can reduce lighting energy use in your home by over 50 percent.  

Lighting controls such as dimmers, timers, and motion detectors reduce light usage by synchronizing lighting directly with living patterns. Motion detectors switch the light on when someone walks into a room, while light sensitive detection adjusts indoor lighting based on the changing levels of outdoor light. 

High tech lighting controls, including whole house systems that offer tie-ins to computer and security systems as well as outdoor lighting, are most effective in new construction that can be hardwired with low-voltage wiring.

Use non-paper-faced gypsum board in moist areas [IEQ183]

<table>
<thead>
<tr>

<td>FEASIBILITY</td>
<td>DIFFICULTY LEVEL: ↑</td>
</tr>
</tbody>
</table>

Minimize mold growth, maintain high indoor air quality and improve durability by using better wall and ceiling finishes. Gypsum board (drywall) is a common building product in the United States and is available in several varieties that resist mold growth. The most reliable is non-paper-faced gypsum board. Paper components absorb moisture because paper is a food source for mold. Non-paper-faced gypsum, originally developed for exterior sheathing, is useful in moist areas such as basements and bathrooms.

In damp areas choose cement board, mortar, or non-paper faced gypsum. Paper-faced gypsum board should never be used as backer for tub or shower surrounds where ceramic tile, marble, or any material with joints or grout lines is used as the finish. While more expensive to purchase than conventional paper-faced products, there are long-term savings in preventing damage from mold growth. It is important to seek comparable data to assess performance of other mold resistant claims by manufacturers, as little independent analysis is available.

Install eco-friendly interior sheathing [MR126]

<table>
<thead>
<tr>
<th>BENEFITS</th>
<th>ENERGY SAVINGS: N/A</th>
<th>WATER SAVINGS: N/A</th>
<th>INITIAL COST: $$</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESOURCE CONSERVATION: 🌳</td>

<td>FEASIBILITY</td>
<td>DIFFICULTY LEVEL: ↑</td>
</tr>
</tbody>
</table>

Paper-faced drywall is the most common and least expensive finishing for interior walls. It is easy to work with and its paper composition is typically recycled from 100 percent post-consumer waste. However, paper-faced drywall is highly susceptible to moisture damage and mold growth; do not use it in moist areas of the home.
Fiberglass-faced drywall is a paperless gypsum panel often used for exterior sheathing and interior walls in mold-prone areas. It contains no cellulose, which supports mold growth. Fiberglass-faced drywall, however, cannot be recycled and because of the fiberglass it cannot be ground for use as a soil amendment.

Choose eco-friendly paints, sheens, and finishes [IEQ185/MR130-131]

Traditional paints, finishes and coatings contain a variety of hazardous chemicals and volatile organic compounds (VOCs) which can be harmful to human health. Choosing zero- or low-VOC paints significantly improves indoor air quality in the home. These products are readily available and come in a wide variety of colors and finishes. Also, choosing appropriate sheens can improve the durability of walls and other finished surfaces. For places that will be washed frequently use sheens with a high “scrubbability” rating.

To further reduce chemicals used in paints, manufacturers recently have introduced products made almost exclusively from plant oils and minerals. When possible, use natural paints, varnishes, finishes and plasters instead of conventional petroleum-based products improve indoor air quality. The increasing availability of natural products has helped make them more competitively priced.

Select eco-friendly wall coverings [MR129/IEQ186]

When it is time to update wall covers, look for low VOC-emitting products. Traditional wallpaper is coated with PVC and plasticizers that over time release chemicals found to interrupt the endocrine system. These impermeable plastic coatings also keep moisture in the walls which can lead to mildew and mold. The discovery of the effects of the production and off-gassing spurred the introduction of many new low-VOC and natural fiber products. These products help reduce airborne chemicals and protect indoor air quality. They also prevent moisture retention behind walls. Natural and low-VOC products are slightly more expensive than traditional products and may need special care when installing, so follow any manufacturing guidelines that come with the product.

Select eco-friendly furniture [MR141-143/146-147/150]

Before purchasing new furniture, consider refurbishing, creative reuse of existing furniture, or buying salvaged items. When purchasing new furniture, select products from companies with responsible business practices that use recycled materials. FSC-certified wood, formaldehyde-free, and low-VOC finishes. Also, spending a little more up front to purchase high-quality, solid furniture and cabinetry will increase the long-term viability of the products and reduce maintenance of the home and will use fewer resources in the long run.
Look for locally manufactured furnishings. Products produced outside the United States and Canada require more resources to transport to New Jersey and tend to have fewer protective controls on formaldehyde and VOC content.

Choose moisture-resistant furniture for longer life while saving money and preserving natural resources. Other ideas to save money and natural resources include selecting products made from certified sustainable wood, reclaimed materials, bamboo, recycled or recyclable metal or plastic, fixable materials, and durable materials.

**Choose furniture/fittings that resist moisture**

Basements in New Jersey tend to be humid. To avoid problems with mold, do not use upholstered furniture or window treatments that absorb moisture easily. These products promote the growth of mold and mildew and degrade indoor air quality. Moldy furniture may be difficult or even impossible to clean, requiring replacement. Whenever possible, choose recycled or sustainably harvested wood furniture over upholstered furniture.

Also be careful of window finishes that may be susceptible to moisture. Finally, avoid carpets in basements. If necessary, use area rugs that can be easily cleaned.

**Select materials that are easy to clean**

When looking for furniture and other items for the home, consider how easy they will be to clean and maintain. Items with reduced maintenance and cleaning needs are replaced less often, mitigating any higher up-front expenses by reducing future costs. Replacing furniture and household items less often conserves resources, reduces the need for new production and eases the burden on landfills.

Materials that are easier to clean require fewer chemical products to be used within the home as well. Products that can be cleaned with natural “green” cleaning agents will also help maintain healthy indoor air quality.

Destination Green
www.destinationgreen.com
Overview and Scope
This project involves the complete restoration of a historical home, originally built circa 1767. The new remodel has three major components. First, the existing part of the home was restored, all systems were updated and a thermal envelope was established. Next, an attached stucco garage built in the 1970's was removed, along with a damaged portion of the home, with plans for a new detached garage to be built later. Finally, a wing which was originally built in 1860 but removed at some point thereafter, is being partially rebuilt. This addition will include an expanded kitchen, family room, master suite, and finished basement.

Design Approach
The homeowners originally started this project with the challenge to show that a historical home could be remodeled sustainably while also adhering to the aesthetics and integrity of the building's past. To this end, the design team used reclaimed, salvaged, and recycled components wherever possible. The owners also desired to reduce their carbon footprint by increasing the energy and water efficiency of his home.

Team and Process
The homeowners planned this project before building green had started to become more common. Since at the time there were very limited resources to assist them, they were inspired to launch a green consulting firm, Green Living Solutions. Therefore they acted as the advisors, choosing all of the green products, features, and materials. The architect was chosen for his experience with older homes and not necessarily for his interest in sustainability, but working with the homeowners, the architect and contractor learned a great deal about green remodeling. The interior designer selected additional detail and materials to further a green result.

Finance
Restoring a historic house properly is inherently more expensive than a standard renovation. Materials used, as well as specialists with experience working on older homes, tend to be more expensive than average. Since the owners have a financial background, they considered the overall costs of operating a home and chose green features that had reasonable payback periods, including efficient lighting and HVAC equipment, better insulation, and a photovoltaic array. The payback periods for all of these features are estimated to be no longer than six years.

Other aspects of green construction were no more expensive than their conventional counterparts, since the homeowners had a good sense of what green products were available.

So far, the owners have reported reduced energy use from the previous owners by roughly 70 percent. When all aspects of the project are complete, they expect to be at 80 percent - 90 percent lower than the energy used by the previous owners despite the fact that the house will be nearly 40 percent larger!

Lessons and Trade-offs
The design team found that most contractors are not fluent in the latest green trends and sustainable practices. A green consultant can make one aware of those options and provide guidance on their viability in the real world; available locally, installed properly, performing up to expectations, etc. Green options tend not to be more expensive if one knows where to look. By becoming aware of green options, homeowners can make sustainable choices without sacrificing comfort, safety, or savings.

“People think of building green as being difficult, more expensive, etc.. It’s at the point where all construction should be done with an eye for sustainability. Green building leads to more durable structures, better indoor air quality, greater comfort, and lower energy costs, not to mention doing our part to reduce greenhouse gases and our reliance on foreign energy sources.”

- Ed Schwartz
List of Green Strategies

**Energy Conservation**
- Improved the thermal envelope, allowing the system to perform much more efficiently
- Utilized a heat-pump-assisted water heating system that dehumidifies the basement, and captures energy to offset water heating needs
- Installed an ultra-insulated hot water tank
- Reduced air infiltration through caulking and air sealing
- Installed expandable spray foam insulation in parts of the attic, the basement ceiling, and the restored addition*
- Installed cellulose insulation in the attic
- Sealed and insulated ductwork
- Excavated dirt crawl spaces which will be replaced with poured concrete over 2” of rigid extruded polystyrene foam board
- Incorporated fly ash in the concrete of the new foundation to reduce the amount of cement needed
- Used Energy Star® rated appliances
- Used CFLs in most light fixtures
- Installed solar tubes for natural daylighting
- Proposed a solar array to offset a significant portion of electricity usage
- Retrofitted fireplaces with inserts that prevent conditioned air from being pulled from the home during use

**Water Conservation**
- Installed low-flow fixtures and toilets
- Utilized an outdoor rainwater harvesting system to reuse rainwater for gardens and landscaping
- Created rain gardens to keep storm water on site and facilitate infiltration
- Replaced part of the driveway with permeable surface

**Indoor Air Quality**
- Removed old asbestos and lead pipes
- Removed lead paint where necessary
- Replaced carbon monoxide producing appliances
- Used low- and no-VOC paints
- Used hardwood and cork flooring instead of carpeting
- Installed an all-climate heat pump with an air filtration system to constantly filter air, provide proper humidity levels, and produce indoor air quality that is better than outdoors

**Resource Conservation**
- Used reclaimed materials wherever possible
- Reused old floorboards for repairs in other parts of the home
- Salvaged front doors from a pre-demolition 1880’s brownstone
- Reupholstered furniture with surplus scrap materials
- Collected stones to be used to build a retaining wall
- Sorted and recycled construction debris

**Sustainable Materials**
- Installed cork flooring in the foyer and kitchen
- Used countertops made from scrap pieces of granite and recycled glass
- Chose closets and cabinets from manufacturers with sustainable practices

---

*To avoid fire hazard when using spray foam materials installed in walls or ceilings, choose an approved, fire resistant thermal barrier with a finish rating of not less than 15 minutes as required by building codes. Rim joists/header areas in accordance with the IRC and IBC, may not require additional protection. Foam plastic must also be protected against ignition by code-approved materials in attics and crawl spaces. See relevant Building Codes and www.iccsafe.org for more information.*
Overview and Scope
The project transformed a 1960’s studio apartment and garage into a 1-bedroom in-law apartment with a kitchen and bathroom, living room and laundry room. A new 3.5 bedroom/2.5 bath home, built to the U.S. Green Building Council’s LEED Silver rating, was built and connected by a covered breezeway to the existing in-law apartment.

Design Approach
Surrounded by an organic beef farm and overlooking pastures and a pond, the homeowner wanted to respect the quiet and beautiful section of Stormville where she lived and aimed to have a lesser impact on the environment throughout the remodeling process. In turn, her desire was to make small changes to the house that would make a huge impact on energy savings and indoor health.

Team and Process
The homeowner was responsible for all changes and upgrades to the home. The renovation to the in-law apartment took place gradually over a period of six years.

Finance
The homeowner developed a marketing program to secure sustainable materials and sponsorships for the project. The program offered three levels of sponsorship (bronze, silver, gold) based on the percentage of discounted or donated materials and/or labor. In return, sponsors received varying levels of marketing and publicity, including recognition on the project’s website. The highest level of sponsorship included participation in a series of open houses over the course of six months. For more information on the project and a full list of sponsors, see (www.monroegreenproject.com).

Lessons and Trade-offs
The homeowner was interested in installing photovoltaic panels but the existing site conditions that included a 200 year old maple tree on the south side of the home and the costly up-front investment did not create a good return on investment, even with New York State’s solar rebates. Instead, the homeowner plumbed the home for future installation of geothermal and solar-thermal, to take advantage of these technologies as they become more cost-effective down the road through better incentives and/or technological advancements.

“You can do things the easy way or do them the right way….only a valiant soul will endure the pressure to do anything the right way....be that valiant soul and change your world.”
- Deborah Monroe

Before remodel

Location of Project: Stormville, NY
Homeowners: Deborah Monroe
Architect: Jordan Valdina
Landscape Architect: Deborah Monroe
General Contractor: Deborah Monroe
Area Affected: 725 sq. ft.
List of Green Strategies

Energy Conservation

• Removed vinyl siding, used house-wrap and added 2-3 inch insulation board to the exterior, and installed fiber-cement siding
• Installed Energy Star® lighting and appliances
• Removed saturated and non-functioning insulation with blown cellulose made from 100 percent recycled newspaper in the attic, bathroom, and under stairs to reduce drafts
• Added European flat panel radiant baseboard on the ground floor
• Installed double pane low-E windows; caulked and used foam insulation around windows to reduce air leakage
• Extended eaves for passive solar heating and cooling and took out roof soffit to eliminate drafts
• Installed chimney for pellet stove that currently uses 1/2 - 3/4 of the amount of pellets and propane used before the changes

Water Conservation

• Replaced a 3.5 gallon toilet from 1952 with a low flow toilet
• Installed low flow faucet in bathroom and water filter on kitchen sink (now uses tap water instead of bottled water)
• Replaced dirt driveway with semi-pervious stone that becomes more solid when wet but still allows for water infiltration
• Extended eaves to protect the home against rain and moisture

Indoor Air Quality

• Repainted entire house with no- or low-VOC paints
• Removed carpet and installed wood flooring upstairs to reduce allergens and eliminate VOC off-gassing from carpet
• Uses green cleaning products

Sustainable Materials

• Replaced trim with FSC-certified wood
• Replaced all sheetrock in bathroom with recycled content sheetrock
Location of Project: Tri-state area

Sustainability Consultants: Homeowners and project team members
Landscape Design: Gaia Gardens
General Contractor: Robert Nagy Building Company
Green Interior Design: Patricia Gaylor Interior Design
Energy Monitoring Services: Christine (Bruncati) Liaukus, R.A, New Jersey Institute of Technology
Area Affected: 3200 sq. ft.

Overview and Scope
A couple with young children purchased the house in which the wife grew up. The home is a 1930s colonial, 3-bedroom, 1.5 bath. Since they had to remodel, they decided to do a “green” remodel with improved energy efficiency, better indoor air quality, and sustainable materials and practices. Their goal was to create a safer, healthier, and more environmentally responsible home in which to raise their family. In addition, the move provided them with a “right-sized” home and a more sustainable location, with a greater number of amenities within walking distance to reduce the need to use a car for transportation. With some additional effort, they decided to pursue a LEED for Homes Platinum rating and use the project to help educate and inspire others about sustainable building and remodeling.

Design Approach
The design team initially struggled with trying to preserve as much as possible of the original home for conservation and sentimental reasons. But in the end it was agreed that the house’s performance was best served by making it a true “gut-rehab.” As a gut-rehab the house is eligible for seeking both the Energy Star® for Home rating and a LEED for Homes Platinum rating from the U.S. Green Building Council. (Only one home in New Jersey is currently rated Platinum, and that is new construction.) The residence is being remodeled using many of the latest environmentally responsible methods and materials. The benefits will include lower operating costs, a smaller carbon footprint, a healthier home, and better environmental stewardship. It will serve as a model of how to “green” an older traditional-style house at different ranges of budgetary investment and how traditional builders can adapt to green building techniques.

Team and Process
The homeowners met with the architect to scope the project and present the variety of initiatives they were interested in pursuing. The architect in turn made suggestions and initiated the design. The homeowners found an interior designer focused on green residential design. They interviewed several builders before deciding on a team that included a green building specialist and a builder who was interested in learning to adapt additional green building practices to his work. The homeowners brought an HVAC contractor on board to explore high-efficiency systems. As the team was assembled, they met and communicated frequently.

Finance
Many of the green methods and materials used can be implemented in any home, with a modest budget, and with a short payback to make it healthier and environmentally friendly. Others are appropriate in a remodel with a bit more investment and longer payback period. Some of the materials chosen, such as flooring, are less expensive than the traditional products. More expensive choices were evaluated using long-term cost savings as a basis, and some choices were pared back to reduce the budget. The homeowners anticipate tremendous savings in energy costs and maintenance. They are grateful to have had the assistance of the project team and partners in keeping costs reasonable, including BASF, Superior Walls, Huston Lumber, Serious Windows, Caroma, Smart Little House, and others.

Lessons and Trade-offs
The biggest challenges for the homeowners, though not really surprises, were the initial difficulties in finding a builder and subcontractors who were knowledgeable and interested in green building. It required research before deciding upon the products that met their needs, since many new options are just now becoming available. The final challenge was managing the budget. The best advice they have is to do a lot of research up front, assemble a capable and enthusiastic team in the design phase (including all of the major sub-contractors) and integrate them in the complete planning process. The team approach helps avoids delays and allows everyone to contribute ideas early in the process, where the costs are lower and benefits potentially higher.
“We’re blending a variety of best practices in green home building while trying to preserve the character of a home that’s been in the family for 50 years. It’s a challenge, but we’ll end up first of all with a very comfortable and healthy home for our family that will have low energy and maintenance costs, and is within easy walking distance of a variety of amenities. In the process of building a home, we’re hoping to pass on the values and responsibility that will make the world a better place for our children and generations to come.”

- Homeowners

**List of Green Strategies**

**Energy Conservation**
- Sealed all leaks in **building envelope** with spray foam **insulation** (seams, outlets, switches)
- Insulated exterior walls and attic roof with closed cell spray foam, which features twice the R-Value of typical batt insulation with no hydrochlorofluorocarbons (HCFCs) or formaldehydes
- Installed low-E glass windows with insulated frames and low **U-factors**
- Designed to maximize daylighting
- Replaced all lighting with efficient **CFL** and **LED** lighting
- Installed occupancy sensors and centrally/remotely controllable lighting
- Installed geothermal ground source **heat pump** for heating and cooling, expected to eliminate most fossil fuel usage
- Installed super-insulated, high-efficiency gas hot water heater, partially heated by geothermal system
- Installed efficient radiant floor heating
- Installed a whole-house energy recovery ventilation system to reduce need for air conditioning
- Designed for solar hot water heater
- Used advanced framing techniques: insulated headers, open insulated corners, 24” O.C. framing, hangers instead of jack studs, and no vents or piping in exterior walls
- Designed integrated shading system to block high angle summer sun and allow low angle winter sun for passive heating

**Water Conservation (Indoors)**
- Installed low-flow aerated faucets/showerheads
- Purchased touch-control kitchen sink faucet
- Installed dual-flush toilets (0.8 gpf and 1.26 gpf)

**Water Conservation (Outdoors)**
- Limited lawn area, reducing water, fertilizer, and pesticide usage and energy necessary to mow lawn
- Purchased **native, drought-resistant plants**

**Resource Conservation**
- Prefabricated foundation walls greatly reduce construction and demolition waste

**Integrated Pest Management**
- Used organic fertilizers and pest control
- Used termite shields and simple screening

**Indoor Air Quality**
- Used low/no-VOC paints and sealants
- Purchased countertops and cabinets made with low-VOC finishes and other formaldehyde-free products
- Built detached garage to prevent auto fumes from infiltrating house
- Installed high-MERV air filter with ventilation systems
- Used no carpeting throughout the home

**Case Study**

**Advanced framing technology**

**Superior building envelope**

**Installed rain barrels and rain gardens** to use rainwater for irrigation and reduce runoff

**Paved driveway and hardscapes with pervious paving materials**
Overview and Scope

This project involved the preservation of and addition to a circa 1869 Victorian home and exterior buildings. Systems and landscape were modified where necessary. A barn of 1,200 sq. ft. was approved for conversion to apartment space.

Sustainable building practices were used where possible that included reused, recyclable, and renewable materials that promote healthy indoor living. Systems were designed to be energy-efficient and water saving.

Design Approach

The goal of this project was to update and restore the historic home and its exterior buildings using methods that integrated sustainable building practices with historic detailing to highlight the existing original qualities of the home.

Team and Process

The owners acted as the general contractor and project managers for this project. Their relationships of over 15 years with most of the contractors helped tremendously with communication throughout the project. They used a true integrated design process and made a commitment to spending scheduled time with all members of the project’s team, allowing for the most efficient communication in order to integrate green design issues, materials and methods.

Finance

In order for a project to be truly sustainable and repeatable, it needs to be financially feasible. In this project, the research involved in determining which products to use, evaluating their impact and locating those products in a timely fashion was the greatest contributor to the increased budget of the project, which exceeded the installation cost of those products. Like many historic houses, the original house had a south-westerly orientation and the owners oriented the addition to take advantage of passive solar. However, while the quality of the workmanship was consistent with previous projects, the attention to details (e.g. increased insulation, choosing a lighter color for the roof as apposed to a black slate, added overhangs and increased attention to the window efficiency and mechanicals) will likely result in a significant reduction in the cost of heating and cooling the house.

Lessons and Trade-offs

The restoration process itself was a reminder of how many of the old world building practices are considered green today; siting a house in relationship to the land and weather, using local, reclaimed, or natural materials, natural day lighting and ventilation. Many of these simple time tested practices were applied to the new “green” addition. As part of the commitment to making this project a true restoration, one of the trade-offs was that the home did not qualify for Energy Star because they decided to restore all of the original windows, re-glaze them, add high performance storm windows and insulate around the windows thoroughly instead of replacing them.

“I believe that restoring an old building is inherently green; it sustains culture as well as resources. It was often a challenge deciding which products and techniques to utilize while trying to balance our commitment to an authentic restoration with our commitment to energy efficiency, a healthy environment and using natural, recycled or long life cycle materials. The green industry changes so rapidly, you have to keep the big picture in mind and make the best choices you can.”

- Lise Thompson

Exterior after remodel
List of Green Strategies

**Energy Conservation**
- Installed low-E windows in the addition to prevent radiant heat from escaping and block ultraviolet rays that can fade many fabrics and materials
- Re-glazed existing windows to help control heat flow
- Replaced broken windows and added storm windows to reduce air leakage
- Installed rigid polyurethane foam insulation to cut air flow throughout the building envelope and reduce heating and cooling loads
- Installed a high-efficiency and high-velocity HVAC system
- Installed a high-efficiency oil-fired burner which doubles as the indirect hot water heater and can be converted to bio-diesel
- Insulated hot water lines with ½” walled rubber insulation
- Designed home to provide for excellent natural day lighting that reduces the demand for artificial lighting during the day
- Oriented renovations toward the southwest providing it passive solar advantages reducing heating loads
- Specified Energy Star® appliances where possible

**Water Conservation (Indoors)**
- Installed copper piping with minimal amounts of PVC
- Added new plumbing fixtures to comply with new energy codes
- Added ½ inch walled rubber insulation to domestic hot water lines allowing for constant hot water and reducing water wastage
- Installed a thermostatically activated recirculating line that heats water as needed saving energy
- Installed an indirect water heater

**Water Conservation (Outdoors)**
- Replaced existing built-in gutters and soffits with 16-ounce copper interior gutters and molding that match the original detailing
- Re-pointed and water proofed the original foundation
- Installed an underground drainage system that collects water from most of the downspouts and the foundation drain and redirects it to a rain garden located below the southern lawn
- Planted rain garden with native plants and with an emphasis on color, appeal to birds and butterflies, and water-absorbent properties
- Protected trees with rock-lined wells
- Used permeable Delaware red stone for driveway

**Indoor Air Quality**
- Gutted the original house allowing it to breathe and removing all the accumulated dust that usually remains inside the walls of old houses
- Used non-toxic, natural materials and no-VOC paint and water based finishes on the flooring and wood trim
- Utilized existing cross ventilation designed for the original house and added a fresh air exchange unit that brings HEPA filtered air into the house every 20 minutes
- Installed a high-efficiency, high-velocity HVAC system with multiple zones that aids in moisture control and the prevention of mold and mildew

**Resource Conservation**
- Preserved all components of the home and site where possible
- Restored moldings, doors, floors, siding, and masonry where possible with local materials
- Used reclaimed antique hemlock flooring to match the original flooring
- Re-glazed existing windows and replaced broken glass with reclaimed antique glass
- Restored barn foundations
- Preserved original roof rafters on the large bank barn while adding a new metal roof and purlins
- Repaired or replaced siding where needed with Pocono Eastern White Pine
- Relocated or replanted trees, shrubs, and other vegetation
- Installed copper gutters and piping that have a long service life and are recyclable
- Used steel beams instead of wood as girders where the original house attached to the new addition
- Installed a new metal roof on the bank barn that will be long lasting and is recyclable
- Utilized reused and local materials where possible
Green Products and Services

Introduction

The purpose of the Green Products and Services is to help homeowners navigate the market with some helpful tips on what to look for when shopping for a particular green home remodeling project. The Guide is organized by building system and lists the general products and services that pertain to remodeling tasks within that system. It includes features and applicable certifications to look for, as well as web links to more information on that product or service. Each item in the Guide also refers to the related REGREEN strategy IDs.

Please note that the New Jersey Green Home Remodeling Guidelines Version 1.0 do not endorse any particular brand or company. It is not the function of the Green Product and Service Guide to direct the consumer to a specific product, but rather to provide a resource to seek out an appropriate manufacturer or service provider to handle remodeling needs.

With the ever-increasing number of green products and services coming into the home remodeling market, finding the appropriate ones can be a challenge. Some manufacturers market products as “green” when in reality they are only marginally better for the environment or whose green features are neutralized by other aspects of their manufacturing or composition. This phenomenon is referred to as “greenwashing” and calls on consumers to seek out references and ensure the true extent of green value.

Product Certification Programs

That being said, there are several leading green product standards and certification programs that can help consumers identify products that meet predefined green criteria. The leading green product standards and programs include:

- Energy Star® - identifies efficient products that reliably deliver energy savings and environmental benefits
- WaterSense – identifies high performing, water efficient products and practices
- Cradle to Cradle - certifies products based on lifecycle of materials used to construct a product and the overall lifecycle of the product
- GreenGuard® Certification Program - certifies products and processes for their low chemical emissions and low toxicity
- Green Seal® - certifies products and practices for their low toxicity and overall environmental impact
- GreenSpec Directory - a published resource on environmentally preferable products
- Forest Stewardship Council (FSC)- certifies wood products coming from forests managed to meet social economic and ecological needs
- Sustainable Forestry Initiative (SFI) - certifies wood products coming from well-managed forests and responsible procurement practices
- National Fenestration Rating Council® (NFRC) - a non-profit organization that administers the only uniform, independent rating and labeling system for the energy performance of windows, doors, skylights, and attachment products.

For more information on various certification programs currently in use by architects and designers see:

- the ecolibrary™matrix - www.thegreenstandard.org/documents/GGNC09_EcoLibCert.pdf
- Gaia Product Profile developed by The Green Standard™ - www.thegreenstandard.org/gaia.html

Two other reputable sources for green products and services are:

- Green Building Advisor that lists products from the GreenSpec Guide to Residential Building Materials www.greenbuildingadvisor.com/
Product Standards for GreenSpec

1. Products Made with Salvaged, Recycled, or Agricultural Waste Content
   a. Salvaged products
   b. Products with post-consumer recycled content
   c. Products with pre-consumer recycled content
   d. Products made with agricultural crop waste material

2. Products That Conserve Natural Resources
   a. Products that reduce material use
   b. Products with exceptional durability or low maintenance requirements
   c. Certified wood products
   d. Rapidly renewable products

3. Products That Avoid Toxic or Other Emissions
   a. Natural or minimally processed products
   b. Alternatives to ozone-depleting substances
   c. Alternatives to hazardous products
   d. Products that reduce or eliminate pesticide treatments
   e. Products that reduce stormwater pollution
   f. Products that reduce impacts from construction or demolition activities
   g. Products that reduce pollution or waste from operations

4. Products That Save Energy or Water
   a. Building components that reduce heating and cooling loads
   b. Equipment that conserves energy and manages loads
   c. Renewable energy and fuel cell equipment
   d. Fixtures and equipment that conserve water

5. Products That Contribute to a Safe, Healthy Built Environment
   a. Products that do not release significant pollutants into the building
   b. Products that block the introduction, development, or spread of indoor contaminants
   c. Products that remove indoor pollutants
   d. Products that warn occupants of health hazards in the building
   e. Products that improve light quality
   f. Products that help noise control
   g. Products that enhance community well-being

| Roofing                 | Roof design minimizes heat island effects. Two types are cool roofs and green roofs. Cool roofs use reflective materials including metals and lightly colored shingles to decrease heat transfer into the indoor environment reducing need for cooling. Green roofs use plants, shrubs, and small trees to replace heat-absorbing surfaces. The plants cool the air through the process of evapotranspiration. Low slope roofs should have an initial solar reflectance of ≥0.65. After 3 years, the solar reflectance must be ≥0.50. Steep-slope roofs must have an initial solar reflectance of ≥0.25. After 3 years, the solar reflectance must be ≥0.15. | New Jersey Department of Environmental Protection (NJDEP): Creating Sustainable Communities – A Guide for Developers and Communities [www.nj.gov/dep/ops/c/Heat_Island.pdf](http://www.nj.gov/dep/ops/c/Heat_Island.pdf)

| Fluorescent lamp | Compact Fluorescent Lamps (CFLs) use less energy, last longer, and contain less mercury than incandescent lamps. Choose lamps with a Color Rendering Index (CRI) of at least 80. For ambient lighting, select a lamp that produces 2700-3000K and a warm or yellowish hue. Task lighting requires lamps that produce 3600-5500K and a bluish or cool hue. | ![Energy Star Logo](image) | USEPA Energy Star®: Compact Fluorescent Light Bulbs

tools like a smoke pencil can detect these air leaks as part of a visual pressure outside air travels in through unsealed cracks and openings, pulls air out of the house, lowering the inside air pressure. As higher via a calibrated fan that mounts on the frame of an existing door and the house or its air infiltration and helps a homeowner prioritize Blower Door Test growth of unwanted organisms.

They are typically selective and can be used agriculturally as biocide pesticides or in other industries to control the infestation and other material extending from an existing structure (usually the side of a house) to provide protection from the sun and rain.

arbors Arbors or pergolas, as they are commonly known, typically consist of a combination of pillars, cross beams, and lattice work upon which vegetation such as vines can be trained and provide shade. Some varieties are attached to existing structures including houses or decks.

Asbestos Asbestos describes a number of naturally occurring, fibrous silicate minerals mined for their utility for thermal insulation, chemical and thermal stability, and high tensile strength. Asbestos is commonly used as an acoustic insulator, and in thermal insulation, fire proofing and other building materials. Many products in use today contain fixed asbestos. It is only hazardous in air and does not pose a hazard if maintained in place.

An awning is a constructed frame covered in a fabric or other material extending from an existing structure (usually the side of a house) to provide protection from the sun and rain.

Backdrafting Backdrafting refers to the process in which a home becomes depressurized from air escaping to the outside and is replaced with air entering from the exterior that may contain combustion products including carbon monoxide.

Baffles Baffles are devices used to control movement of light, fluids, wind, and other forces.

Biocides Biocides are chemicals used to destroy living organisms. They are typically selective and can be used agriculturally as pesticides or in other industries to control the infestation and growth of unwanted organisms.

Blower Door Test The Blower Door Test measures the leakiness of the house or its air infiltration and helps a homeowner prioritize problem areas. This test uses pressure differences created by air flow via a calibrated fan that mounts on the frame of an existing door and pulls air out of the house, lowering the inside air pressure. As higher pressure outside air travels in through unsealed cracks and openings, tools like a smoke pencil can detect these air leaks as part of a visual inspection process.

borate-treated foam board Borate-treated foam board is an insulation panel that is pest- and fire-resistant.

building envelope The building envelope of a structure is descriptive term that separates its interior from the exterior.

capillary breaks Capillary breaks, typically made of elastomeric asphalt coating or a polyethylene sheet, are installed between footings and the foundation wall to prevent water absorption.

carbon dioxide (CO₂) Carbon Dioxide is a gas byproduct of the burning of fossil fuels and other forms of combustion.

carbon monoxide (CO) Carbon Monoxide is a toxic gas byproduct of combustion that is both odorless and colorless. Sources of its production include wood stoves, fireplaces, gas stoves, and furnaces among others.

chromated copper arsenate (CCA) Chromated Copper Arsenate is a wood preservative used to prevent decay from insects and microbial agents. Its contents include chromium, copper, and arsenic and is limited to restricted use.

cellulose Cellulose fibers from recycled newsprint can be applied as a form of insulation that is flame, mold, and pest resistant, provides thermal and sound insulation, and resists settling.

Cellulose insulation Cellulose fibers from recycled newsprint can be applied as a form of insulation that is flame, mold, and pest resistant, provides thermal and sound insulation, and resists settling.

cement board Cement board is a non-combustible, water-durable, and mold-resistant panel that is typically used under tile and other finishes for interior and exterior use.

Certified sustainable wood Certified sustainable wood meets specific criteria developed by organizations such as the Forest Stewardship Council to promote responsible wood harvesting and condemn the exploitation of local peoples.

Cladding Wall cladding is a nonstructural material used as the exterior covering for the walls of a building.

Closed-cell Closed cell (spray polyurethane foam or SPF) is typically installed at a density between 2.0 to 3.0 lbs. per cubic foot, and is manufactured with non-ozone-depleting blowing agents.

Color Rendering Index (CRI) The Color Rendering Index (CRI) is a 1-100 scale that measures how colors appear under different light sources. A light source with a CRI of 80 or higher is considered acceptable for most indoor residential applications.

Color temperature Color Temperature defines the color and warmth or coolness of a light source. Color temperature is measured in Kelvin (K) temperature. Contrary to what is expected, higher Kelvin temperatures (3600–5500 K) are considered cool and lower color temperatures (2700–3000 K) are considered warm.

• A color temperature of 2700–3600 K is generally recommended for indoor general and task lighting.

• Task lighting calls for cool light which produces a higher contrast and is better for visual tasks.

• Warm light is more flattering to skin tones and clothing and is recommended for living spaces.
**Glossary**

**combustion** Combustion is the chemical process of the release of gasses in the process of burning of a fuel.

**combustion appliances** Combustion equipment refers to appliances such as stoves, water heaters, and clothes dryers that burn fuels. It is important to make sure that these appliances work correctly and are properly ventilated to prevent carbon monoxide, a byproduct of combustion, from entering the home.

**commissioning** Commissioning ensures that a home's mechanical systems have met their design intent, operate and interact optimally.

**Compact Fluorescent Lights (CFLs)** Compact fluorescent lights are the miniature fluorescent lights that can screw into standard light fixtures that conventionally use incandescent bulbs. CFLs are more energy-efficient and durable than incandescent bulbs.

**concrete formwork** Concrete formwork is a concrete walling system used for its insulating properties and durability.

**cooling load** Cooling load refers to the amount of heat that is to be removed from a space by a cooling system.

**copper quat** Copper quat is a wood treatment containing both copper oxide and quat as didecyldimethylammonium chloride (DDAC) to prevent decay and fungi and insects.

**creosote** Creosote is a wood preservative distilled from coal tar. Typically applied to utility poles and railroad ties, can only be used for commercial purposes.

**crown size** The crown size of a tree refers to the diameter of the portion of a tree that has foliage.

**damper(s)** Dampers are adjustable plates located in the flue of a fireplace that prevent heat from escaping when it isn't in use.

**deciduous tree(s)** Deciduous trees are species that shed their leaves for part of the year.

**diffuser** Diffusers are circular, square or rectangular air distribution outlets which are usually located in the ceiling. They are comprised of deflecting blades which discharge supply air in various directions. Diffusers are designed to mix the conditioned air entering the space with the air already contained in the space.

**disposable respirators** Disposable respirators or filtering facepieces can be made of cloth or paper and are designed to clean the air as you breathe it to prevent you from inhaling irritating substances.

**double-hung window(s)** Double-hung windows have two vertically sliding sashes, each closing a different part of the window.

**drain pan** Drain pans provide a basin to catch any fluids leaking from a piece of equipment such as a clothes washer.

**dripline** The dripline of a tree refers to the area of ground located directly under the circumference of its outermost branches. This area indicates where the tree should be watered as opposed to the base of its trunk where it can develop root rot.

**Duct Blaster Test** A Duct Blaster Test utilizes a fan and a pressure gauge to measure the amount of air escaping from the ductwork of a home by pressurizing the system.

**duct cleaning** Duct cleaning refers to the cleaning of heating and cooling system components in forced air systems, including the supply and return-air ducts, registers, grilles, diffusers, heat exchangers, heating and cooling coils, drain pans, fan motor, fan housing, and the air handling unit.

**duct mastic** Duct mastic is a sealant used to reduce air leakage in duct systems. Its flexibility enables it to contract and expand.

**duct squeezing** Duct squeezing refers to the use of under-sized ducts in an HVAC system in tight spaces that accelerates the air flow creating excessive noise and increases the system's operating costs.

**ducting system** Ducting systems are networks of ducts or formed sheet metal that direct the flow of air from central HVAC units.

**Energy Star® for Homes** Typically 20-30% more efficient than standard homes, Energy Star qualified homes must meet certain criterion including energy saving features.

**Energy Star® Thermal Bypass Checklist (TBC)** The Energy Star Thermal Bypass Checklist consists of guidelines for a home inspection that may reveal any opportunities for energy efficiency improvements.

**erosion** Erosion is the process by which soil and rock are worn away through water, wind, ice and wave transport.

**evergreen trees** Evergreen trees retain their needles or leaves through the winter and into the next growing season.

**extruded polystyrene (XPS)** Extruded polystyrene is a plastic foam insulating material that is resistant to moisture, rot, mold, and corrosion.

**fiber cement** Fiber cement siding is composed of sand, cement, and cellulose that make it more durable than wood, termite- and water-resistant, and non-combustible.

**fiber cement siding** Fiber cement siding is composed of sand, cement, and cellulose that make it more durable than wood, termite- and water-resistant, and non-combustible.

**flame spread rating** Flame spread ratings (FSRs) are used to evaluate "the surface burning characteristics of building materials including ignition temperature, smoke toxicity, and flame-spread." Building materials are compared to the FSR scale where inorganic reinforced cement board is 0 and red oak is 100.

**fly ash** Fly ash is a byproduct of coal-fired electric power generation that can be combined with cement in concrete to improve its strength.

**form-release agents** Form release agents assist in the removal of molds by producing a film that separates them from concrete.

**formaldehyde** Formaldehyde is a chemical compound used in products including paper towels, photographic film, glues, and inks among others. It is important to avoid products containing formaldehyde whenever possible as they off-gas potentially hazardous pollutants.

**formaldehyde-free** Formaldehyde-free products don’t contain any formaldehyde. Formaldehyde is a chemical that off-gasses creating air pollution and should be avoided whenever possible.
Glossary

Forest Stewardship Council (FSC) -Certified Wood  The Forest Stewardship Council certifies wood that complies with its standards disapproving of illegally harvested wood, wood harvested in violation of traditional and civil rights, in forests in which High Conservation Values (areas particularly worthy of protection) are threatened through management activities, from conversion of natural forests, and from areas where genetically modified trees are planted.

gasket  Gaskets are rings typically made of rubber or metal to create a liquid-tight seal between two joints.

geofabric  Geofabric or landscape fabric is a synthetic material used to control erosion and prevent weed growth.

glazing  Window glazings are compounds applied to glass to reduce the amount of heat transfer between the interior and the exterior of a building and/or the ultra-violet (UV) light passing that passes through it.

green roof  Green roofs are contained vegetative roof coverings that provide a variety of economic, ecological, and aesthetic benefits including reducing the heating/cooling loads of the building, reducing runoff, and producing oxygen among others.

extensive  Extensive green roofs are 6 inches or shallower and are frequently designed to satisfy specific engineering and performance goals.

intensive  Intensive green roofs may become quite deep and merge into more familiar on-structure plaza landscapes with promenades, lawn, large perennial plants, and trees.

green treated  “Green treated” wood refers to wood treated by chromated copper arsenate (CCA) to resist fungal decay and pests. CCA treated wood use is limited primarily to poles, pilings, and bridge timbers.

gypsum  Gypsum is a mineral found in sedimentary rock formations in a crystalline form known as calcium sulfate dihydrate. It is typically used in wall board to create a non-combustible core.

gypsum board  Gypsum board or drywall is used in various paneling applications that consists of a paper-faced non-combustible gypsum core.

hardwiring  Hardwiring refers to the use of cables or electric wire to connect electronic components.

heat exchanger(s)  Commonly used in space heating, refrigeration, air conditioning, and other applications, heat exchangers are devices built for efficient heat transfer from one medium to another.

heat island effect  The heat island effect occurs in densely urbanized areas where impermeable roof and pavement temperatures increase during the summer, elevating the air temperature. This in turn generates a greater demand in energy consumption for cooling systems which concentrates air pollutants and creates smog. Runoff from these heated surfaces reaches waterways where it can increase the water temperature and negatively affect ecosystems.

heating/cooling loads  Heating and cooling loads refer to how much warm or cool air must be produced in order to maintain a building's temperature.

Heating, Ventilation, and Air Conditioning (HVAC) Systems  Heating, Ventilating, and Air Conditioning systems process and supply air through ductwork helping to regulate humidity and temperature in buildings to provide safe, healthy, and comfortable conditions.

heavy metals  Heavy metals including copper, selenium, and zinc are elements found in the earth’s crust that can't be degraded or destroyed. Some in small doses are vital to bodily functions while high concentrations can be lethal.

HEPA filtered air scrubbers  High efficiency particulate air or HEPA air filters are a type of high-efficiency air filter that remove at least 99.97% of airborne particles down to a size of 0.3 micrometers (µm) in diameter.

HEPA vacuum  High efficiency particulate air or HEPA filters are a type of high-efficiency air filter that remove at least 99.97% of airborne particles 0.3 micrometers (µm) in diameter. HEPA filter used in vacuum cleaners trap the fine particles (such as pollen and dust mite feces) which trigger allergy and asthma symptoms.

high-recycled content  Products of high-recycled content are made mostly with materials that have already been used.

Home Energy Analysis  A Home Energy Analysis considers possible measures that can be taken to improve a home's energy efficiency based on certain criteria.

Home Performance Audit  Home Performance Audits are conducted to assess the energy efficiency of a home and evaluate possible energy saving measures.

house wrap  House wrap, typically made of polyethylene, is a breathable material used to prevent moisture and wind from entering the home.

IICRC S500 Guidelines  The Institute of Inspection, Cleaning and Restoration is an independent, non-profit certification body that sets and promotes standards for the inspection, cleaning and restoration service industry. These guidelines provide specific practical standards for water damage restoration.

impervious surface  Impervious surfaces such as concrete and conventional asphalt do not allow water penetration.

infiltration  Infiltration is the process by which water seeps through the ground where it may reach a water body or an aquifer.

infrared camera  Infrared cameras are used to detect thermal variations and may be used in conducting energy efficiency analyses.

infrared imaging  Infrared imaging detects thermal variations and may be used in conducting energy efficiency analyses.

Insulated Concrete Forms (ICFs)  Insulated concrete forms typically made of expanded polystyrene (EPS) or extruded polystyrene (XPS), are used to mold concrete. They remain in place permanently serving as a thermal barrier.

insulated pre-cast concrete wall systems  Insulated pre-cast concrete wall systems consist of concrete panels that are cured off site. The installation of these panels to construct a foundation or a wall is much faster than the curing time of a formed concrete wall.
Integrated Pest Management (IPM) Integrated pest management is an effective and environmentally sensitive form of pest management that utilizes monitoring, prevention, and control techniques.

Kelvin (K) Kelvin is a universally accepted base unit used to measure temperature. One degree in Celsius is equivalent to one degree in Kelvin. Water freezes at zero degrees Celsius, which is approximately 273.16 Kelvin.

latent cooling load The latent cooling load of an HVAC system is the amount of heat energy produced by moisture from indoor and outdoor sources that needs to be removed from a home in order to maintain a constant temperature.

Light-Emitting Diodes (LEDs) Light-Emitting Diodes are electronic light sources that use less energy than incandescent bulbs or compact fluorescent lamps.

load calculations Load calculations are formulas used to derive the heating, cooling, or electrical loads of a system.

long-wave radiation Long-wave radiation is emitted from both the earth and the atmosphere influencing temperature.

loose-fill insulation Loose-fill insulation made of fiber, foam, or other recycled waste materials is able to be blown in places where the installation of other types of insulation is difficult.

louver(s) Louvers are vertical slats on a window, blind, or shutter that are angled in such away to allow in light and air while providing a shield from rain, direct sunlight, and noise.

low-E Low-E or Low-Emissivity glazings are metal or metal oxide coatings applied to windows to reduce heat flow.

low-VOC These products contain smaller amounts than standard materials of volatile organic compounds (VOCs) that can off-gas chemicals and cause air pollution.

low-VOC duct mastic Duct mastic is a sealant used to reduce air leakage in duct systems. Its flexibility enables it to contract and expand. Using low-VOC (volatile organic compounds) products reduces the off-gassing of harmful chemicals promoting a healthy indoor environment.

moisture meter Moisture meters are devices used to measure the amount of water in a given substance that help determine if it is ready to use.

mold amplification sites Mold amplification sites are locations where mold has built up over time. Typical sites of indoor mold buildup are damp cellulose materials (e.g. wallboard paper, wallpaper, carpet backing, damp papers); debris in ventilation ducts, in carpets, or in mattresses or upholstered furniture; poorly maintained humidifiers; insulation on which organic film has accumulated; constantly humid painted, caulked or plastic surfaces (e.g., windowsills, shower stalls, cold air return vents); and potted plant soils.

mortar Mortar is a sandy material that combines with cement and water to bond tile, stone, brick, or concrete blocks.

National Air Duct Cleaners Association (NADCA) The National Air Duct Cleaners Association (NADCA) was formed in 1989 as a non-profit association of companies engaged in the cleaning of HVAC systems. Its mission is to promote source removal as the only acceptable method of cleaning and to establish industry standards for the association.

National Fenestration Rating Council (NFRC) The National Fenestration Rating Council (NFRC) is a non-profit organization that administers the only uniform, independent rating and labeling system for the energy performance of windows, doors, skylights, and attachment products.

native plants/species/trees Native plants are species of plants or trees that occur in the region in which they evolved.

natural ventilation Natural ventilation systems utilize pressure differences caused by wind or the buoyancy effect (created by differences in temperature or humidity) to circulate fresh air through buildings.

non-CFC sealant Non-CFC sealants don’t contain the ozone depleting chemicals chlorofluorocarbons (CFCs).

non-combustible Non-combustible materials are incapable of burning.

non-porous Non-porous materials lack any spaces where gasses or liquids can pass through.

old growth timber Old growth timber comes from old growth forests where trees must compete for sunlight, growing slower, developing more dense rings increasing the strength of the wood.

open-cell Open cell, low-density polyurethane foam (typically 0.5 lbs. per cubic foot) is produced with a water or carbon dioxide blowing agent.

optimal load calculations The optimal load of an HVAC system can be calculated to determine the amount of energy required for it to operate most efficiently.

Oriented Strand Board (OSB) Oriented Strand Board is similar to plywood and consists of cross-layered rectangular wood strands fixed together with waterproof heat-cured adhesives.

over-sizing Over-sized ducting of HVAC systems may lead reduced indoor air quality and an imbalance of air flow distribution.

Pascal The Pascal is the standard unit of the measure of pressure equal to one Newton/square meter.

passive solar Passive solar home design considers the materials and arrangements of windows, walls, and floors to utilize solar energy for heating in the winter and reduce solar heat gain in the summer.

passive solar design Passive solar home design considers the materials and arrangements of windows, walls, and floors to utilize solar energy for heating in the winter and reduce solar heat gain in the summer.

passive solar heating Passive solar heating incorporates design and specific materials to heat a building directly using energy from the sun rather than a mechanical HVAC system.
**Glossary**

**permeability** The permeability of a substance is a measure of how well liquids can pass through it.

**petroleum-based** Petroleum-based products are made from the raw natural resource petroleum, such as oil and natural gas.

**phenol formaldehyde** Phenol Formaldehyde (PF) is commonly used in polymer resins as a safer alternative in pressed-wood materials off-gassing less formaldehyde than products that use Urea Formaldehyde (UF).

**photovoltaic (PV) power** Photovoltaic power refers to the conversion of light into an electric current through a device such as a solar panel.

**planting bed** Planting beds are areas designated in a landscape for planting.

**plenum(s)** Plenums are boxes made of sheet metal that connect to the outlet of an air handler or furnace to which other ductwork can attach.

**plumbing chase** A hollow wall area accommodating piping used for drain waste or vent in plumbing systems.

**polysiocyanurate** Polysiocyanurate is a plastic consisting of closed-cell foam that contains a low-conductivity gas (usually hydrofluorocarbons or HCFC) in its cells. It has a high thermal resistance and is used as insulation that is available as a liquid, sprayed foam, or foam board.

**polystyrene** Polystyrene is a plastic foam that comes in extruded or expanded forms that are used in various building applications for their insulating properties.

**porous** Porous materials have spaces through which gases and/or liquids can pass.

**portland cement** Portland Cement consists of hydraulic calcium silicates that when combined with water harden to become water-resistant. It is one of the most widely used cements by concrete producers and are available in various levels of strength and durability.

**post-consumer recycled content** Post-consumer recycled products consist of materials that were previously used by consumers.

**pressure treated** Pressure treated wood undergoes a process in which a chemical preservative (usually chromate copper arsenate (CCA) or less toxic amine copper quat (ACQ)) is applied under high pressure and is intended primarily for exterior use.

**programmable thermostat** Programmable thermostats are devices used to control a home's heating/cooling system that can be set to turn off when no one is home and then back on when the home will be occupied to reduce the cooling load.

**radiant barrier** Radiant barriers are installed in homes to reduce summer heat gain and winter heat loss, and hence to reduce home heating and cooling energy usage. All radiant barriers have at least one reflective (or low emissivity) surface, usually a sheet or coating of aluminum.

**radon** Radon is a carcinogenic (cancer-causing) radioactive gas produced from the decay of uranium in rock, soil, and water.

**rainscreen** Rainscreens are used to reduce the exposure of exterior walls to precipitation, preventing moisture intrusion and the decay of materials. Every rainscreen consists of vented or porous cladding, an air cavity, a drainage layer on support wall, and a rigid, water-resistant, airtight support wall.

**rain gardens** Rainwater gardens are constructed landscape systems that utilize native plants to collect runoff.

**reclaimed materials** Reclaimed materials are salvaged architectural components that save money, are better for the environment and are aesthetically pleasing.

**recycled content** Products with recycled content are made from materials that have already been used in another product.

**reflective roof** Reflective roofs made of metal or that have reflective coatings reduce the cooling load of a building by decreasing the amount of heat that is absorbed through the roof.

**refrigerant** A refrigerant is a compound used in a heat cycle that undergoes a phase change from a gas to a liquid and back for use in refrigerators/freezers, air conditioners, and other appliances.

**return duct** Return ducts prevent the pressurization of closed rooms from supply air by allowing air to flow back to the central return grille.

**return grille** Return grilles are grates used to cover the ends of return ducts.

**return register** Registers are vent covers that are typically used on forced air ducts. They have a pre-attached damper or set of louvers to help control airflow.

**rigid glass fiber insulation** Rigid glass fiber insulation are sheets or molded-pipe coverings made of plastic foams or fibrous materials that provides thermal and acoustic insulation.

**rigid insulation** Rigid glass fiber insulation are sheets made of plastic foams or fibrous materials that provides thermal and acoustic insulation.

**rigid insulation board** Rigid glass fiber insulation boards are sheets made of plastic foams or fibrous materials that provide thermal and acoustic insulation.

**rim joist** Rim joists are the boards that cap the ends of the floor system.

**roof garden** Roof gardens are landscape systems constructed on a building's roof to reduce runoff, decrease heat island effect, remove air pollutants, and add aesthetic value among other purposes.

**runoff** Runoff is water that doesn’t infiltrate the ground but instead flows above ground or through storm drains to a water body.

**R-Value** The R-value of a material indicates its resistance to heat transfer. A high R-value is better than a low R-value.

**Seasonal Energy Efficiency Ratio (SEER)** The seasonal energy efficiency ratio measures the efficiency of a central cooling system.
over an entire season comparing the number of BTU’s produced to watt-hours consumed.

**sensible cooling load** The sensible cooling load of a home refers to heat gain from the collective impact of conduction, convection, the exterior, people, and appliances.

**sheathing** Sheathing refers to a building material that is used to cover exterior wall framing or roof trusses.

**shortwave solar radiation** Shortwave solar radiation is direct energy from the sun.

**single-package models** Single-package model HVAC systems have all of their components, including evaporators, cooling coils, compressors, and condensers, contained within one unit.

**single-pane window** Single-paned windows have only one piece of glass separating the interior and exterior of a home. Double-pane windows are considered to be much more energy-efficient.

**six-sided containment** Six-Sided Containment refers to the insulating of all six sides of frame wall cavities in unconditioned, concealed spaces.

**smog** Smog is a combination of fog and smoke from combustion characterized by poor visibility and adverse health affects.

**smoke pencil** Smoke pencils detect air pressure differences between two spaces by emitting smoke that leaks through any cracks or openings.

**soffit vent(s)** Soffit vents are applied to the underside of a construction element and are perforated for intake ventilation.

**soil gases** Soil gases include radon and other gases that come from a ground source. Some of these gases such as radon are toxic and may require that a system be installed to prevent them from entering the home.

**Solar Heat Gain Coefficient (SHGC)** The Solar Heat Gain Coefficient is the fraction of incidental solar radiation admitted through a window.

**Solar Renewable Energy Certificate (SREC)** SREC stands for Solar Renewable Energy Certificate and is a tradable certificate that represents all the clean energy benefits of electricity generated from a solar electric system. Each time a solar electric system generates 1000 kWh (1 MWh) of electricity, an SREC is issued which can then be sold or traded separately from the power.

**solar tubes** Solar tubes consist of a clear dome that collects sunlight into a highly polished and reflective tube that reflects the light down to a diffuser on the ceiling. They are sufficient to light a small room, hallway, or staircase.

**solar water heating** Solar water heaters or domestic hot water systems utilize storage tanks and solar collectors to provide hot water for a home saving both energy and money.

**split systems** Split HVAC systems have their components including evaporators, cooling coils, compressors, and condensers located inside and outside of a building.

**spray polyurethane** Spray polyurethane foam (SPF) is a plastic insulation that expands and hardens after being installed as a liquid.

**sprayed foam insulation** Spray foam is a plastic insulation that expands and hardens after being installed as a liquid.

**stormwater recharge** Stormwater recharge is the active restoration of groundwater resources by way of stormwater drainage systems.

**Structural Insulated Panels (SIPs)** Structural Insulated Panels are made from a thick layer of foam (polystyrene or polyurethane) sandwiched between two layers of Oriented Strand Board (OSB), plywood or fiber-cement.

**supply duct(s)** Supply ducts made of formed sheet metal deliver air to interior spaces from an HVAC system.

**supply register** Registers are vent covers that are typically used on forced air ducts. They have a pre-attached damper or set of louvers to help control airflow.

**sustainably harvested wood** Sustainably harvested wood considers the social, economic, and ecological factors associated with logging to ensure long-term productivity while satisfying the desires of people.

**task lighting** Task lighting, often described as “cool” lighting, produces higher contrasts that are better for seeing. Task lighting sources emit temperatures between 3600-5500K.

**thermal bridging** Thermal bridging occurs when high thermal conductivity materials such as steel and concrete create pathways that bypass thermal insulation resulting in heat loss.

**Thermal Bypass Checklist (TBC)** The Thermal Bypass Checklist is a comprehensive list of building details where thermal bypass, or the movement of heat around or through insulation, frequently occurs due to missing air barriers or gaps between the air barrier and insulation.

**Thermal Bypass Inspection** The Energy Star® Thermal Bypass Checklist is a comprehensive visual inspection of building details where thermal bypass, or the movement of heat around or through insulation, frequently occurs due to missing air barriers or gaps between the air barriers and the insulation.

**thermal paints** Thermal paints are finishes with insulating properties that prevent heat transfer.

**thermal scan** A thermal scan of a home using infrared or heat sensing imaging detect where insulating improvements can be made.

**thermographic (infrared) imaging** Thermographic imaging is used to detect thermal variations and may be used in conducting energy efficiency analyses.

**topsoil** Topsoil is the outermost layer of soil primarily composed of organic matter.

**transom** Transoms are the windows above doors that serve to allow in sunlight and release warm air.

**tree well** Tree wells are the holes where trees are planted.
Glossary

trellise(s) Trellises are structures that usually consist of latticework to support vegetation including vines and other creeping plants.

U-Factor The U-factor of a window assembly indicates its rate of heat loss.

U.S. Green Building Council’s Leadership in Energy and Environmental Design for Homes (LEED-H) certification LEED for Homes is a rating system that encourages the building of green homes that use less energy, water and natural resources, create less waste, are healthier and more comfortable.

unconditioned spaces Unconditioned or unfinished spaces including attics and crawlspace can provide a variety of energy saving opportunities.

vapor barrier Vapor barriers are materials that reduce the rate at which water vapor can move through a material.

vegetative swale Vegetative infiltration swales are planted areas intended to catch runoff where it can be filtered and enter the ground.

vermiculite insulation Vermiculite-insulation is a naturally occurring mineral, favored for its absorbent, lightweight, fire-resistant, odorless characteristics. Pre-1990 vermiculite insulation products are likely to contain some traces of asbestos associated with the mine where the vermiculite was collected.

Volatile Organic Compound(s) (VOC) Volatile Organic Compounds (VOCs) are off-gassed from certain solid or liquid products and may cause negative health effects when inhaled.

warm-edge spacer Warm-edge spacers are used to separate panes of glass in insulated windows and conduct less heat than standard aluminum spacers.

water heater blanket Water heater blankets are used to insulate water heaters with R-values less than 24.

water table The water table refers to the upper surface of ground water.

weatherization Weatherization involves procedures that protect a building from the elements.

weatherstrip Weatherstripping is the sealing of cracks or holes around windows, doors and other openings exposed to the exterior of a building with caulk, foam, rubber strips, or other materials that can be used to reduce airflow between the interior and the exterior.

wet footing Wet footings occur when there is groundwater in the footing trench.

whole house fan Whole house fans located on attic floors ventilate warm air from interior spaces to the outside while depressurizing the home to draw in cool air from open windows.

wicking Wicking is a term used to describe moisture that moves from the foundation up into walls by capillary action.

wind baffle Wind baffles are structures used to control the movement of wind.

windbreak Windbreaks are barriers typically consisting of trees, shrubs, crops, fences, and other materials to direct wind flow.

wiring conduits Wiring conduits are pipes or liners used as raceways to carry and protect conductors.

wiring raceways Wiring raceways are surface-mounted on interior walls to house wiring to maintain the integrity of a continuous wall system.

woven socks Woven socks filled with wood chips can be placed strategically at a site to control soil erosion and runoff.

zero-VOC Zero-VOC products don’t contain any volatile organic compounds that create air pollution by off-gassing chemicals.

zero- or low-VOC Zero-VOC products contain no volatile organic compounds and thus do not negatively impact air quality from off-gassing chemicals.

zone controller A zone controller connects multiple thermostats to a single HVAC system.

zoning HVAC zoning strategically divides a building into zones where each has its own thermostat for independent temperature control.
New Jersey’s climate requires homes to perform efficiently in both hot and cold temperatures. Homeowners can use high-efficiency appliances and HVAC equipment, passive solar techniques, proper ventilation, air sealing, and durable roofs to ensure high performance and diminish the home’s total energy consumption. The result will be a reduction in space heating, cooling and water heating requirements. These strategies promote overall building energy efficiency and durability throughout the year.
Weatherization and Energy

How to Use the Guidelines

Health and Safety
- HS1 - Nuisance and Toxic Dust Control
- HS2 - Cautious Materials - Asbestos and Lead
- HS3 - Mold
- HS4 - Radon

Green Home Maintenance and Housekeeping

Building Envelope
- Conduct a Home Performance Audit and diagnostic tests [IDP2/EA51-54]
- Install or upgrade insulation [EA49]
- Air seal to reduce infiltration [IDP55]
- Weatherstrip doors and windows [EA58]
- Upgrade or replace existing windows [EA56/59]
- Provide moisture management strategies [IDP24]
- Use appropriate window glazing [EA60]
- Upgrade existing exterior door [EA57]
- Install window shading system [EA62]
- Install a durable wall cladding [MR119]
- Provide a durable and reflective roof [MR120]

HVAC
- Follow standards for mechanical design [EA63]
- Provide controls and zoning for HVAC [EA64]
- Use ceiling fans for natural ventilation [EA65]
- Install programmable thermostats [EA67]
- Select high-efficiency HVAC equipment [EA66]
- Conduct duct tightness test [EA68]
- Maintain HVAC systems [EA69]
- Seal and insulate HVAC system [EA70]
- Make sure ductwork is clean [EA71]

Lighting and Electrical
- Provide daylighting [EA83]
- Provide appropriate lighting [EA84]
- Install energy-efficient lighting [EA85]
- Provide appropriate indoor lighting controls [EA90]

Plumbing
- Insulate water heater [EA80]
- Insulate hot water pipes [EA81]
- Reconfigure plumbing for efficiency [EA77]
- Utilize solar water heating [EA101]

Equipment
- Select high-efficiency clothes washer [EA92]
- Select an energy-efficient refrigerator [EA93]
- Choose an energy-efficient dishwasher [EA94]
- Install energy-efficient cooking appliances [EA95]
- Select energy-efficient office equipment [EA99]
- Consider on-site renewable energy [EA102]

Case Studies

Green Products and Services

Glossary of Terms
How to Use the Guidelines

Organization of the Guidelines

The Guidelines are organized into chapters by major project type: Kitchen, Bath and Living Spaces, Finished Basement and Major Addition, Weatherization and Energy, and Outdoor Living and Landscaping.

Each chapter includes the following:

- How to Use the Guidelines
- Health and Safety
- Green Home Maintenance and Housekeeping
- Best Practice Strategies
- Resources and References
- Case Studies
- Green Products and Services
- Glossary of Terms

Getting the Most from the Strategy Write-ups

The Guidelines provide information on best practice strategies for each project type. These strategy write-ups are organized by building system and follow the order of the 2008 REGREEN Residential Remodeling Guidelines (i.e., IDP2), which are incorporated with permission. Figure 1 describes the information available.

**Figure 1**

A *Home Performance Audit* identifies energy upgrades for cost savings. Diagnostic tests examine the whole house and look at the interactions between all systems in a home: air leakage, insulation, combustion appliances, heating and cooling systems, and ventilation. Several free online energy audit tools are available for homeowners. The NJ Office of Clean Energy’s Home Energy Analysis Tool offers specific recommendations based on the age of the home; average energy usage, the types of appliances, and other criteria. It is available on the NJ Office of Clean Energy website: www.njcleanenergy.org.

**Title and REGREEN Strategy ID** – The strategies in the REGREEN Residential Remodeling Guidelines 2008 inspired most of the strategies in these Guidelines. Where appropriate, the strategy references the related REGREEN strategy ID.

**Shopping Cart** – The cart denotes entries in the Green Product and Service Guide located in the back of each project chapter.

**Strategy Description** – This write-up provides an overview of each strategy and its environmental benefits.

**Glossary Term** – Acronyms and green building terms are highlighted in bold and defined in a glossary at the back of each chapter.
**Call-out Boxes** - The call-out boxes in Figure 2 highlight information of special importance. These include the following types of information:

- **Tips** - useful hints or practical facts for accomplishing a strategy
- **Incentive** - sources of financial assistance
- **New Jersey Bio-Region** - New Jersey has 5 bio-regions, each with unique elements and environmental features to consider when remodeling
- **Building Age** - a home’s age can inform needed repairs and call out special circumstances
- **Caution** - on occasion, there are hazards associated, so items are called out for safety reasons

**Hazard Symbol** - Symbols were developed to advise users of certain health and safety threats related to specific strategies. The symbols, which appear below, reference the guidance on Health and Safety located at the beginning of each section.

- **HS1** – Nuisance and Toxic Dust Control
- **HS2** – Hazardous Materials - Asbestos & Lead
- **HS3** – Mold
- **HS4** – Radon

**Web Link** - When viewing this document electronically, the websites will hyperlink, however, occasionally website links change. In most cases, the site provides a seamless link to the new address. If this is not the case, users may need to copy and paste the link into the browser address bar. At the time of publication the hyperlinks in this report were all functional.

**Scorecard** - The scorecard, Figure 3, provides a snapshot of the environmental benefits, initial costs, and difficulty levels associated with a particular strategy. Both qualitative and quantitative information was used to assign scores to each strategy.

It is divided into two parts: 1) Benefits and 2) Feasibility.

**Graphic icons were developed for each impact category.**

**BENEFIT Key**

1 icon = low benefit, 2 icons = medium benefit, 3 icons = high benefit

**FEASIBILITY Key**

$ low initial cost, $$ medium initial cost, $$$ high initial cost

↓ low difficulty level, ↑ medium difficulty level, ↑↑ high difficulty

The icons above have been developed to graphically describe the ratings that follow.

**BENEFITS**

- **Energy Savings**

To help meet its greenhouse gas reduction responsibility, in 2007 New Jersey passed carbon dioxide (CO$_2$) reduction goals, i.e., achieve 1990 emission levels by 2020, followed by a further reduction of emissions to 80 percent below 2006 levels by 2050. The state has also established renewable energy and energy efficiency targets. Green remodeling strategies utilize renewable energy sources such as solar, geothermal, and wind to net a lower CO$_2$ footprint.
### Water Savings

Water conservation reduces water use both inside and outside the home. Within the home this may include low-flow fixtures. Outside the home this may refer to using native plants that have lower water requirements or rain barrels to collect rainwater for reuse on the lawn and garden. Water management includes providing proper moisture control at footings, slab perimeter, and foundation walls as well as using porous paving materials to encourage stormwater recharge for reduced runoff.

### Air Quality

Americans spend up to 90 percent of their time indoors where air quality can be more polluted than outdoors. Pollutants range from allergens such as mold, mildew, fungus, and dust mites to toxins, such as asbestos, and volatile organic compounds like formaldehyde and benzene found in building materials and a number of household items including pressed-wood furniture, computer ink, carpeting, and conventional household cleaners and cosmetics.

### Resource Conservation

Resource conservation means using materials that are durable and easy to maintain with low embodied energy (the energy used in resource extraction, manufacturing, shipping). These come from renewable sources or are produced from waste, recycled materials, or salvaged from other uses. Avoiding building materials that deplete natural resources, such as old-growth timber, and materials made from toxic or hazardous substances improves nature's ability to provide goods and services.

### FEASIBILITY

#### $ Initial Cost

Cost is always a consideration for remodeling projects. Evaluating the cost of a recommended green remodeling strategy provides homeowners with a better sense of the relative costs and benefits of each recommended measure.

Costs come in two forms, so it is important to consider both in assessing feasibility. The first reflects initial costs of the strategy compared to conventional practices. A second consideration to make is the pay-back period or life-cycle cost. The pay-back costs are less obvious and are often project specific, but they can have significant environmental and economic value that factor into the overall cost. For more information on average costs, savings, and payback periods of typical energy efficiency improvements, see the Energy Efficient Rehab Advisor at [www.rehabadvisor.pathnet.org/](http://www.rehabadvisor.pathnet.org/). For customized results, have an energy professional conduct a thorough energy audit of your home.

- $ Less than $500
- $$ $500-$5,000
- $$$ Greater than $5,000

#### Difficulty Level

Time is money and expertise is gained over time. Some people may consider a Home Performance Audit strategy in the ‘medium’ category because although relatively straightforward to act on, it requires experts with custom equipment to prepare an accurate assessment. Implementing the findings from a Home Performance Audit becomes a ‘high’ difficulty category as space heating and cooling systems, ventilation, water heating, appliances, climate and even site factors need to be integrated to assure desired energy improvements across ‘ALL loads’ and to avoid negative unintended consequences. It is expected that ‘high’ difficulty strategies may also be dangerous for the basic homeowner to undertake.

- Easy to Do It Yourself (DIY) - little previous knowledge necessary
- Task for an Experienced DIYer or Professional - may require additional effort and higher learning curve than conventional strategy it replaces
- Task for an Expert/Certified Professional - high learning curve; new technique; requires specific green knowledge

---

Health and Safety

Green remodeling poses hazards typical of many other home renovation or remodeling projects because of the age of the homes (given that they are more likely to contain older and use more hazardous materials) and the incentive for green remodeling to replace older or damaged building systems. New Jersey homeowners considering green remodeling should anticipate potential emissions of hazardous air contaminants during removal of old building materials. The risks associated with improper removal of materials containing asbestos, lead, mold or even fiberglass insulation are minimized by understanding and following the steps listed here prior to initiating work. For complex situations, consider hiring professionals.

General hazard recognition and risk reduction information for the following potential renovation-related risks are contained in this section:

**HS1 – Nuisance and Toxic Dust Control**

**HS2 – Hazardous Materials - Asbestos & Lead**

**HS3 – Mold**

**HS4 – Radon**

**HS1 – Nuisance and Toxic Dust Control**

Construction projects involving demolition of existing sheetrock, plaster, wood, brick or concrete products in ceilings, walls or floors of a home will release dust as these materials are ripped, sanded, ground, pulverized or crushed. Control of dust emissions during the pouring of solids or from transferring of small particles is controlled in industrial facilities. Homeowners planning renovation projects should also consider steps to minimize the release and maximize control of dust in the environment. These nuisance dusts, when released from the point of origin into the air of the home, tend to remain suspended in the air for very long periods of time, and as such, will be transported with air currents caused by open doors, cracks around and beneath doorways, forced air heating and cooling ductwork, and even by the air currents caused by persons walking in and out of dusty areas, to other areas of the home. At a minimum, allowing the uncontrolled release of nuisance dusts from any demolition project, as well as those created from sawing, sanding, or grinding of newly constructed materials (e.g., sheetrock, spackling, wood dust etc.) presents unnecessary and difficult dust cleanup demands for affected living spaces. At their worst, susceptible occupants of homes where uncontrolled nuisance dusts are allowed to escape into adjacent living spaces may temporarily experience eye, nose, or throat irritation. Asthmatics may experience adverse respiratory distress when exposed to high levels of nuisance dust particles.

There are several simple steps to minimize potential hazards of nuisance dust during remodeling.

1. Remove unnecessary porous and non-porous materials (e.g., draperies, bedding, upholstered furniture, children's toys, clothing, etc.) from the project area.
2. Seal the project area from the remainder of the home using polyethylene sheeting at doorways and at inlets to any forced air supply or return registers within the project space.
3. Consider installing HEPA filtered air scrubbers in the project area and discharging the exhaust air through an adjacent window using a tight fitting flexible duct through a sealed window opening (consider surrounding security requirements). Use a lightweight section of facial tissue at the doorways to confirm that air pressure is moving from the clean adjacent living space and into the project area (not the other direction) so that air leaks from the clean home into the dirty renovation area. This will reduce any potential for dusts from the renovation area to enter the adjacent areas of the home.
4. Periodically during the work session and after every work session, HEPA vacuum the renovation area following renovations to remove accumulated surface dust, without re-suspending it into the air.
HS2 – Hazardous Materials - Asbestos & Lead

When removing old building materials, know that they contain hazardous materials, which while intact present little to zero risk to occupants, but when removing can create airborne emissions and increase health and safety risks. This is especially true of asbestos and lead, and, possibly to a lesser extent, fiberglass. Removal of asbestos, lead or fiberglass needs to be planned and conducted with care to minimize exposures to airborne dust from these materials.

Asbestos

Asbestos is a mineral that has been mined in the U.S. since the early 1900's. Its superior heat resistance properties, combined with its lightweight, high-tensile strength, and non-corrosive qualities, made it an ideal building material for buildings constructed between 1940 and the late 1980's. Asbestos was banned as a building material in the U.S. after scientists concluded studies linking long-term occupational exposures to damaging respiratory health including asbestosis (scarring of the lung), lung cancer, and mesothelioma (cancer of the lining of the lung). Because intact asbestos presents no increased health risk, there is no requirement for removing it from existing homes. However, when it is disrupted, pulverized or suspended in air, the potential for inhalation of asbestos fibers increases risks of exposure. While health effects develop only after decades of long-term occupational or environmental exposure, homeowners should take particular care to prevent unintentional release of asbestos into the air of their homes during green remodeling efforts so that children and others are not exposed.

Asbestos is commonly found in older homes (constructed between 1940 and the late 1980's) in the following building materials:

- Pipe and boiler insulation
- Sprayed on fireproofing insulation
- Acoustical tiles and wall coverings
- Floor tiles
- Roof shingles
- Siding shingles

There is no requirement that homeowners remove asbestos-containing materials from homes. However, if removal is part of a green building remodeling project, material should be tested by a New Jersey licensed asbestos control monitor, and if determined to contain asbestos, be removed by a New Jersey licensed asbestos contractor. The number of the state program to contact for assistance in identifying qualified personnel to assist homeowners to safely address any possible asbestos concerns is (609) 292-7837.

General information about asbestos and its proper management and disposal can be found at the Department of Health website: www.state.nj.us/health/iep/asbestos.shtml and the Department of Environmental website: www.nj.gov/dep/dshw/rrtp/asbestos.htm.

Lead

Lead was in residential paints prior to 1978. It was banned after that time due to the significant health affects to children inhaling or consuming dusts from lead-based paints. Because of the hazards posed by dusts and chips of lead-painted surfaces, any remodeling or renovation which impacts painted surfaces of homes constructed prior to 1978 needs to be inspected by a New Jersey licensed lead inspector. If lead paint is identified, it should be safely removed by a state of New Jersey licensed contractor. They can safely remove lead-based paint and conduct follow-up surface lead testing to confirm that the removal was successful. Information on lead-based paint and qualifications for lead inspectors and contractors can be found at: www.state.NJ.us/health/iep/documents/pb_advisory_bulletin.pdf.

Contact the New Jersey Department of Health and Senior Services at (609) 292-7837 with any questions.

Fiberglass

Fiberglass insulation is a manufactured glass-wool-like material used as an insulation and sound absorption material in homes, schools, automobiles and consumer products since the 1970's. Fiberglass insulation can be safely installed if handled properly; any prolonged skin, eye or respiratory contact with fiberglass can cause temporary irritation. During renovation, wear loose fitting clothing and gloves to reduce skin contact, eye glasses or goggles to reduce eye exposure, and N95 disposable respirators (available from any home improvement store) if high levels of fiberglass dust are expected during removal or installation. More information on fiberglass safety precautions and handling recommendations can be found at the American Lung Association website at: www.lungusa.org/site/pp.asp?c=dvLUK9O0E&b=35439 or call the American Lung Association in New Jersey at (908) 687-9340.
HS3 – Mold

Mold contamination of building materials is not limited to older homes. Homes of any age can develop mold if moisture from leaky pipes, roofs, foundations, accumulates in the presence of dust, wood, paper or other cellulose-containing materials at normal room temperatures or high relative humidity (76 percent) for as little as 48 hours. Standing moisture around building materials such as wallboard, carpets, insulation, wood or other cellulose containing materials can cause mold. Many mold spores are known human allergens and produce toxins which may cause irritation or central nervous system effects. Because of vast differences in susceptibility, or if individual health impacts related to elevated mold spore exposure are of concern, consult a trained and experienced occupational/environmental health physician.

In addition to the above, mold damage can occur if flooding from faucets, showers, toilets (above the trap), is not completely dried within 48 hours of the incident. Floods from dirty water sources such as washing machines, dishwashers or sewers may contain high levels of bacteria, viruses, and protozoa which, along with potential mold growth, present additional risks.

If mold amplification sites occur, remove the affected material using methods that prevents unintentional dispersal of mold spores and the source of moisture intrusion. The U.S. Environmental Protection Agency indicates that small areas of mold growth (less than 10 square feet) can be cleaned or removed by homeowners themselves using precautions to prevent exposure and reduce spread of spores to adjacent areas. When mold contaminated areas exceed 10 square feet, special precautions including erecting containment barriers and the use of specialized HEPA vacuum devices should be used by trained professionals. When mold contamination occurs in excess of 100 square feet, professionals need to clean using full containment of the area (see www.epa.gov/mold/moldguide.html).

If mold growth from dirty water floods occurs, take special precautions to prevent skin, eye, oral and inhalation contact, and hire trained professionals to clean up in accordance with U.S. EPA: www.epa.gov/iaq/flood/index.html and IICRC S500 guidelines

Homeowners should anticipate that the amount of mold contamination shown on the outside of a piece of drywall or paneling may be less than the amount that will be exposed when wall cavities are opened up. If there is any doubt, consider hiring a professional Certified Industrial Hygienist (CIH) to evaluate the extent of damage before attempting to remove contaminated building materials yourself.

HS4 – Radon

Radon is a radioactive gas that comes from the natural decay of uranium in the ground. It is odorless, tasteless and invisible, and can only be detected through specialized tests. Radon enters homes through openings such as cracks and joints in the foundation, sump pits and openings around pipes. The home traps radon inside and it can build up to high levels.

Radon is the second leading cause of lung cancer in the United States, resulting in 15,000 to 22,000 deaths annually. It is the leading cause of lung cancer for non-smokers.

Radon concentrations can vary from house to house. The radon concentration in a home depends on a number of factors, including the amount of uranium present in the soil, the permeability of the soil, the number of openings in the foundation and air pressure differentials. Any home can have a radon problem, regardless of whether it is old or new, well sealed or drafty, or with or without a basement.

The New Jersey Department of Environmental Protection recommends radon testing for all homes in New Jersey. If the radon concentration is 4 pCi/L or higher, a radon mitigation system is recommended. There is no safe level of radon since lung cancer can result from very low exposures to radon, however, the risk decreases as the radon concentration decreases. If the radon concentration is less than 4 pCi/L, a mitigation company can be consulted to determine whether the radon level can be brought down still further. Radon levels have been brought to less than 1 pCi/L in sixty percent of the homes mitigated in New Jersey. Mitigation systems can also help reduce the potential for accumulation of volatile organic compounds that may be released from soil water vapor in areas where ground water contamination is an issue.

Radon test kits are commercially available at most home improvement stores, however, test conditions and locations may make data interpretation difficult or inaccurate. Carefully follow the kit directions to ensure proper use and confidence in the results. The New Jersey Department of Environmental Protection has issued licensing requirements for radon testing firms, and has a list of qualified professionals to perform radon testing and mitigation, see www.njradon.org.

Green Home Maintenance and Housekeeping

Introduction

Your home is one of the biggest investments of your life. Can ‘going green’ protect your investment and make it safer, more enjoyable and save you money? Yes.

This guide to Green Home Maintenance and Housekeeping practices will improve the health, comfort and environment for your family, and save you money, most directly by reducing your utility bills. The guide’s focus on ‘Energy’ savings, improvements to ‘Indoor Air Quality’, effective and efficient ‘Household Waste Management’ and conserving ‘Water’ all add measurable benefits to you and high return on your investment. Routine checks and repairs will ensure your home’s appearance and proper function. By following these recommendations, you will also prevent more expensive damage from occurring.

Weatherization and Energy

You can save energy and money at home by making small changes and following some easy, practical solutions/tips

1. Easy energy saving kitchen tips.
   • Air dry dishes instead of using the dishwasher’s drying cycle.
   • Recommended temperatures for the refrigerator are 37°F to 40 °F for the fresh food compartment and 0° to 5°F. for the freezer compartment.
   • Cover liquids and wrap foods stored in the refrigerator. Uncovered food release moisture and make the compressor work harder.
   • Instead of preheating and using a stove’s larger oven, consider using a pressure cooker, slow cooker or a microwave; for small meals use the toaster oven rather than your large stove/ oven.
   • Use a covered kettle or pan to boil water.
   • Match the size of the pan to the heating element.
   • Keep range-top burners and reflectors clean; they will reflect the heat better and save energy.
   • In natural gas appliances, look for blue flames; yellow flames indicate the gas is burning inefficiently and an adjustment may be needed. Consult the manufacturer or your local provider.

   Note: Homes with combustion appliances should install carbon monoxide (CO) alarms to prevent accidental death by carbon monoxide poisoning. For more information, see the U.S. Environmental Protection Agency, “Indoor Air Quality Carbon Monoxide Fact Sheet” available at www.epa.gov/iaq/co.html

2. Laundry tips
   • The biggest energy and cost savings comes from alternatives to the dryer. Air dry your clothes on clothes lines or drying racks.
   • Wash your clothes in cold water using cold-water detergents whenever possible.
   • Wash and dry full loads. If you are washing a small load, use the appropriate water-level setting.
   • Wash and dry towels and heavier cottons in a separate load from lighter-weight clothes.
   • Don’t over-dry your clothes. If your machine has a moisture sensor, use it.
   • Clean the lint filter in the dryer after every load to improve air circulation.
   • Use the cool-down cycle to allow the clothes to finish drying with the residual heat in the dryer.
   • Periodically inspect your dryer vent to ensure it is not blocked.

3. Optimize energy usage in your home
   • Lower the thermostat on your hot water heater to 120°F.
   • Drain a quart of water from your hot water tank every three months to remove sediment that impedes heat transfer and lowers the efficiency of your hot water heater. Follow the manufacturer’s advice.
   • Plug home electronics into power strips; turn the powers strips off when the equipment is not in use.
• Turn off your computer and monitor when not in use.
• Replace all bulbs in your home with Compact Fluorescent Lamps (CFLs).

4. Check your home insulation and prevent air leaks.
• Air seal the attic floor joists wherever wires, heating ducts, or plumbing pipes come through; caulk or foam the top plate of the partitions below the attic floor. Install gaskets and 4 inches of rigid foam insulation on top of the attic access panel or access door.
• Air seal the band joists in the basement using 2 inch rigid foam and foam-in-a-can.
• Add additional insulation if the home is built before 1980, or to achieve an insulation R-value of R-38 to R-50. (Air seal first.)
• Prevent air leaks when the fireplace is not in use. Keep the fire damper tightly closed and use inflatable chimney balloons that fit beneath the fireplace flue.
• Use kitchen exhaust fan covers that keep air from leaking in when the exhaust fan is not in use.

5. Maximize the efficiency of your HVAC system
• Set the thermostat as low as is comfortable in the winter and as high as is comfortable in the summer. Typically, thermostats are set between 65°F and 70°F for heating and 72°F and 78°F for cooling.
• Using a 2-inch paint brush, apply duct mastic to all accessible duct work joints or holes.
• Clean or replace filters on furnaces once a month or as is needed.
• Remove the register covers and caulk the duct work in the wall, floor and ceiling to prevent conditioned air from being lost in the wall or ceiling cavity. This is especially important in the ceilings directly below the attic.
• Clean warm-air registers, baseboard heaters, and radiators as needed; make sure they are not blocked by furniture, carpeting or drapes.
• Bleed trapped air from hot-water radiators once or twice a season; call a professional if required.
• Place heat resistant radiator reflectors between exterior walls and the radiators.
• Minor duct repairs are easy to make, but it is best to get a qualified professional for insulating, sealing or repairing any ducts.
• For summer cooling, install a whole house fan to pull cool air through the house and exhaust warm air through the attic.
• Avoid placing lamps or TV sets near your air-conditioning thermostat.
• Keep the air conditioning unit in the shade and not in the sun.
• Add plantings to shade air conditioning elements in sunny locations. Leave sufficient space so air flow is not obstructed and access is available in the event of a need for service.

6. Your home's energy performance can be improved by improving the performance of the windows.
• Lower the amount of gas or electricity used to heat and cool your home. In summer, open windows at night to let in cool air and close both windows and shades during the day to keep out heat. During winter, do the opposite. Open shades in the morning to capture sunlight and close them at night to retain the heat.
• Install exterior or interior storm windows.
• Repair and weatherize windows.
• When installing new windows, consider double-glazed, low-E windows with high performance glass.
A Home Performance Audit identifies energy upgrades for cost savings. Diagnostic tests examine the whole house and look at the interactions between all systems in a home: air leakage, insulation, combustion appliances, heating and cooling systems, and ventilation. Several free online energy audit tools are available for homeowners. The NJ Office of Clean Energy’s Home Energy Analysis Tool offers specific recommendations based on the age of the home, average energy usage, the types of appliances, and other criteria. It is available on the NJ Office of Clean Energy website (www.njcleanenergy.org).

Certified professionals can conduct a more comprehensive Home Performance Audit. This often includes a combination of visual inspections and diagnostics tests to identify opportunities to repair or upgrade aspects of the building envelope or mechanical systems. The following strategies are common elements of a more comprehensive Home Performance Audit:

- **Blower Door Test** – Blower door tests help determine a home’s airtightness. Proper airtightness is important for reducing energy use and drafts due to air leaks, avoiding moisture problems, and regulating indoor air quality. It is important that auditors use a calibrated blower door, which allows them to test airtightness before and after recommended changes have been implemented, and to verify that the work completed solved the problems.

- **Thermographic inspections** - Thermographic inspections or infrared scanning uses specially designed infrared video or still cameras to make images (called thermograms) that show surface heat variations. Thermograms help determine whether and where a home needs insulation. Because wet insulation conducts heat faster than dry insulation, thermographic scans can also detect roof leaks and other moisture problems.

- **Thermal Bypass Inspection (TBI)** – The Energy Star® Thermal Bypass Inspection (TBI), and a corresponding checklist, is designed to check for missing or incorrectly installed insulation and sealing of penetrations and air gaps. It is most commonly performed for new construction and major renovations. Reducing thermal bypass, or the movement of heat around or through insulation, is important as they can lead to comfort issues as well as higher utility bills. For more information, see the Energy Star® Thermal Bypass Checklist: www.energystar.gov/index.cfm?c=bldrs_lenders_raters.thermal_bypass_checklist

The NJ Office of Clean Energy Home Performance with Energy Star Program (www.njcleanenergy.com/) provides reduced fee home energy audits and a listing of certified energy auditors on its website.

Install or upgrade insulation

Insulation slows down the heat flow through a home’s building envelope - the walls, attic, roof and basement. In the winter, insulation slows heat loss and helps prevent moisture buildup. During summer months, it reduces heat gain and helps keep a home cool.

Insulation is rated according to its **R-Value**, or its ability to resist heat flow, with a high R-Value being a greater resistance. Adding insulation with a higher R-Value can cut heating and cooling costs anywhere from 15 to 45 percent, depending on factors such as the original amount of insulation in the home, house size, air leaks and personal energy use and living habits.

Tips

Prepare for a Blower Door Test

- Close windows and open interior doors
- Turn down the thermostats on heaters and water heaters
- Cover ashes in wood stoves and fireplaces with damp newspapers
- Shut fireplace dampers, fireplace doors, and wood stove air intakes

Incentive

New Jersey’s Clean Energy Program (NJCEP) offers low-price Home Performance Audits and other incentives. www.njcleanenergy.com/residential/home/home

The Database of States Incentives for Renewables and Efficiency (DSIRE) provides information on state, local, utility, and federal incentives and policies that promote renewable energy and energy efficiency. www.dsireusa.org/

Incentive

Federal tax credits may be available for added insulation to walls, ceilings, or other part of the building envelope. See the Tax Incentive Assistance Project: www.energystatetaxincentives.org/general/legislative.php.
Building Envelope

In colder climates, adding extra insulation is more cost-effective than installing a radiant barrier.

Insulation in older homes will have settled and at best be dusty or dirty so new attic insulation is typically installed on top of old insulation.

Vermiculite Insulation was used until it was discovered that vermiculite ores from some sources have naturally occurring asbestos in trace amounts. This type of insulation is only a health concern when someone comes into contact with it; while it is contained, it is not determined to be a health risk. If a remodeling or renovation project involves removal of this type of insulation, certified professionals will be needed to safely remove or contain the material. For more information, see EPA website www.EPA.gov/asbestos/pubs/verm.html.

Use a re-useable dispenser gun to seal the harder to reach spots and increase your resource conservation.

To assure combustion safety, New Jersey building code requires that foam insulation be covered by a non-combustible material such as gypsum board. It is advisable to test for carbon monoxide before air sealing efforts.

Certified energy auditors conduct an insulation check as part of a comprehensive home performance audit. They can determine the R-Value of the home’s current insulation and measure air leakage. They then can recommend where air sealing and insulation should be added.

Thorough air sealing should be done before insulating. Insulation alone does not protect against air leakage; moist air can damage the insulation and reduce its effectiveness. Adding insulation before air sealing may make some air leaks difficult to access. Avoid thermal bridging by installing a layer of continuous insulating sheathing over frames or joists.

The general rule-of-thumb is to install insulation on any surface separating a heated space from an unheated space; walls, ceilings, attics, floors and ducts should be well-insulated. One of the best places to begin installing or upgrading insulation is in the attic as a significant amount of heat can be transferred through the roof. Installing attic insulation is also a relatively easy job for do-it-yourselfers.

There are four basic types of insulation:

- Batts and blankets—Batts and blankets are made from mineral fibers, such as fiberglass and rock wool, and typically have a value of R-3 per inch. They are available in widths suited to standard spacings of wall studs and attic or floor joists; 2x4 walls can hold R-13 or R-15 batts and 2x6 walls can have R-19 or R-21 products. Use this type of insulation below floors, above ceilings, and within walls. Batts and blankets can be installed by homeowners or professionals.

- Loose-fill insulation—Loose-fill insulation is often made from fiberglass, rock wool, or cellulose in the form of loose fibers or fiber pellets and typically has a value of R-3 to R-4 per inch. This type of insulation works best in places where it is difficult to install other types of insulation such as building cavities and attics. Loose-fill insulation is usually blown in by professional installers.

- Rigid insulation board—Rigid insulation board is often made from fiberglass, polyurethane, or polystyrene and typically has a value of R-4 to R-8 per inch. Use this type of insulation on basement walls and as perimeter insulation at concrete slab edges, and in cathedral ceilings. For interior applications it must be covered with 1/2-inch gypsum board or other building-code approved material for fire safety. For exterior applications, cover with weather-proof facing.

- Spray foam—Spray foam insulation comes in two forms: open-cell and closed-cell. The closed-cell foams typically have a higher R-value (R-7 to R-8 per inch) than open-cell foam (R-5.6 to R-8 per inch). Most foam insulation products have a higher R-value per inch than fiberglass batt insulation. This type of insulation provides both insulation and an air barrier, and is suited well for filling small spaces — such as window jambs, small stud bays, rim joist areas, and for sealing around electrical boxes and other penetrations. Spray foam insulation should be applied by professional installers using special equipment to meter, mix, and spray the foam into place. Most foam materials can now be used with foaming agents that don’t use chlorofluorocarbons (CFCs) or hydrochlorofluorocarbons (HCFCs), which are harmful to the earth’s ozone layer.

Air infiltration or leakage may contribute to as much as 30 percent of a home’s heating and cooling costs. The most common sources of air infiltration are the attic, crawl space, or basement, and around windows, doors, and chimneys. Other sources include plumbing chases, electrical outlets, attic accesses, dropped ceilings and leaky ducts.

Reduce air leakage as much as possible before adding insulation and provide controlled ventilation as needed. First, identify air leaks in the home (see Conduct a Home Performance Audit and diagnostic tests [IDP2, EA51-EA54] above). A good rule of thumb is to seal the high and low air leaks first. Start by plugging holes and leaks in the attic and basement, then move to the exterior wall, and look for smaller leaks around doors, windows and electrical switches and outlets. Use

Air seal to reduce infiltration

Energy savings: ☀️

Water savings: 🌊

Feasibility

Initial cost: $

Difficulty level: ♂

Benefits

Air infiltration or leakage may contribute to as much as 30 percent of a home’s heating and cooling costs. The most common sources of air infiltration are the attic, crawl space, or basement, and around windows, doors, and chimneys. Other sources include plumbing chases, electrical outlets, attic accesses, dropped ceilings and leaky ducts.

Reduce air leakage as much as possible before adding insulation and provide controlled ventilation as needed. First, identify air leaks in the home (see Conduct a Home Performance Audit and diagnostic tests [IDP2, EA51-EA54] above). A good rule of thumb is to seal the high and low air leaks first. Start by plugging holes and leaks in the attic and basement, then move to the exterior wall, and look for smaller leaks around doors, windows and electrical switches and outlets. Use
caulk to seal openings up to \( \frac{1}{4} \) inch such as cracks and gaps between window frames and siding. For larger gaps, add a backing material before caulking or use a spray foam sealant. After all the larger air leaks have been sealed, weather-strip doors and windows.

Weatherstrip doors and windows [EA58]

When replacing doors or windows is not feasible, consider weatherstripping. Weatherstripping stops drafts coming into the home from under or around doors and windows; on newer windows and doors it is fairly easy. On average, doors have more gaps and larger cracks than even loose-fitting windows.

Weatherstripping kits for doors are readily available at local hardware stores, but finding replacement weatherstripping that matches the old can be a challenge. Steel or custom door kits may be harder to find. Check with the manufacturer in these cases. Typical weatherstripping kits include two side strips, a top strip, and fasteners. Consider a door sweep if the floor, carpet or rug is below the bottom of the door frame. The cost of materials will pay for themselves in energy savings within one year, saving about 10 percent on heating and cooling loads.

Proper sealing means weatherstripping the entire door jamb in one continuous strip on both sides. For air sealing windows, apply weatherstripping between the sash and the frame. In both cases make sure that the weatherstripping is the right thickness so as to not impair the ability of doors or windows to open and close.

Double-hung windows are trickier than casement windows to weatherstrip, requiring two types of weatherstripping. The type of weatherstripping needed depends on the type of window and the situation. Angled or V-shape spring-type weatherstripping is nailed to the frame and bottom sash to seal double-hung windows. Pliable weatherstripping is sponge-like and installed in the channels and sash of wood casement windows. Compressible felt strips are not as durable at these other options but good for use with warped windows or for windows that are not often opened.

Upgrade or replace existing windows [EA56/59] 

Determining whether the home’s windows need to be updated or replaced starts with a Home Performance Audit (see strategy IDP2/EA51-54), which will reveal if some or all of the windows leak. Visual inspection may also reveal window problems. Are any of the windows cracked? Do they open to allow fresh air to enter? Are there any windows without storm windows?

Upgrade or replace single-pane with double-pane windows with low-E or spectrally-selective glass to save 10 to 25 percent per year on heating. To help offset the up-front cost, check for incentives from federal tax credits and through state and local utilities. If window replacement is not in the budget and old single-pane windows are in good condition, install storm windows in the winter months. Upgrading the sash alone can also save money. Storm windows can reduce heat loss through the windows by 25 percent to 50 percent. Storm windows also protect against impacts from rain, ice and snow. Bear in mind that good windows installed badly will not achieve expected savings, so see the link in the resources section for tips on “How to Hire an Expert Installer.” Finally, windows that are properly sealed and caulked prevent leakage of air in and out of the house and provide a protective barrier from water and noise. (For more information, see Weatherization and Energy: Weatherstrip doors and windows [EA58]).
Provide moisture management strategies

A dry house is a more durable house and therefore extends the value of the home, a precious resource. The cost and complexity of moisture management strategies depends on what steps will be undertaken. Consider the costs of not properly managing moisture in terms of the durability of the structure of the building and to a home’s indoor air quality, as mold can quickly reach toxic levels.

The building envelope plays a key role in the total performance of the building, so most moisture management strategies focus here. Several strategies keep the building envelope drier. Roof overhangs and overall sealing of any roof and wall penetrations are major examples. Incorporate a house-wrap or weather barrier when replacing the exterior cladding such as upgrading the house siding. Create a drainage plane, such as house-wrap with texture placed under siding, to allow hidden wet spaces to dry more quickly.

The integrity of the building envelope can be challenged by moisture in any state: 1) liquid in the form of rainwater penetration, 2) solid such as ice and snow, and 3) vapor, such as relative humidity. If these conditions are not managed properly, they can lead to decay of the home, creating permanently wet conditions that also affect indoor air quality. [See additional window, wall and foundation strategies in this section to understand how to best manage moisture.]

Use appropriate window glazing

Correctly designed glazing systems reduce energy usage and enhance natural daylighting in the home. Optimizing window glazing is a passive solar design that considers the orientation of the sun and adjusts window glazing accordingly. Glazing is measured by its Solar Heat Gain Coefficient (SHGC). The SHGC gauges the amount of solar heat energy transmitted through the window glazing. Higher heat energy - indicated by a high SHGC - is desirable for south-facing windows in northern climates. Design east and west windows with a lower SHGC to keep the heat gain down in summer. To best balance the temperature of the building envelope, glazing as part of a whole window design assures that all issues are factored in for optimal comfort and energy savings. SHGC is considered with a window’s R-Value rating to assure optimal window performance.

Window performance also depends on the connection to the adjacent envelope elements so these need to be properly water-managed. A glazing system has high resistance to water vapor transport but must be integrated with the building envelope’s rainwater management design as framing design and construction techniques also impact water intrusion.

When replacing windows, select units with features that improve energy performance. These features include double or triple glazing, warm-edge spacers, gas filling between the panes (argon, krypton or a mixture of both), and a variety of coatings on the glass including low-emissivity (low-E) coatings. All of these features improve the U-factor by reducing the heat loss through the window.
Upgrade existing exterior door [EA57]

An exterior door that is old, improperly installed, or not well-sealed can contribute significantly to energy losses in a home. If the home has older doors or if installing a new door can be included as part of a larger home improvement project, replacing them will result in lower heating and cooling costs. Adding a storm door can be a good investment if a home's existing door is old but still in good condition, however, adding a storm door to a newer, insulated door is not generally worth the expense since it won't save much more energy. When selecting a door for energy efficiency, consider its energy performance rating and look for the Energy Star® and National Fenestration Rating Council labels. Check for federal tax credits and state and local incentives for qualifying doors.

Install window shading system [EA62]

Roughly 40 percent of the unwanted heat build-up in the home comes in through windows. High performance windows can partly compensate for poor orientation and/or poorly placed windows (See Use appropriate window glazing EA60 above). However, shading devices can supplement the benefits of high-tech windows and add an extra layer of protection against the sun. Shading on south and west facing windows helps reduce heat gain in the summer. In the winter, when the sun is lower in the sky, windows permit sunlight to pass through the window to warm the interior. Deciduous trees on the southeast, south and southwest areas of the home can provide considerable shade and natural cooling during summer months. These same trees will lose their leaves during the winter months, allowing sunlight to heat homes during the day. Although both exterior and interior shades can control heat gain, exterior shading devices - such as roof overhangs, awnings, louvers, shutters, and solar screens - are most effective since they block sunlight before it enters the windows.

Roof overhangs can help keep unwanted summer midday sun from heating a home, and can protect the home from rain and potential moisture damage. The drawbacks of overhangs are that they are difficult to add unless the remodel includes plans for work on the roof, and there is no way to retract them. While there is not a universally accepted method for calculating sizes for overhangs, the U.S. Department of Energy offers the following general guidelines for moderate climates:

- Moderate climates: below 6,000 heating degree days (HDD) (at base 65°F [18°C]) and below 2,600 cooling degree days (CDD) (at base 75°F [22°C]) (HDD and CDD data is available from local weather services.)
- Locate shadow line at window sill using the June 21 (summer solstice) sun angle.
- Sustainable by Design offers the following shareware design tools for calculating solar angles and designing window overhangs: www.susdesign.com/tools.

Awnings are often made of fabric or metal and can be stationary or retractable. A light-colored awning also reflects sunlight. To take advantage of the desirable winter heat gain, homeowners should remove awnings for winter storage or buy retractable ones.

Louver operate like exterior mini-blinds. They can have vertical or horizontal slats to control the level of light entering a home and, depending on the design, can be adjusted from either inside or outside of the house.

Shutters are moveable wooden or metal coverings that, when closed, keep sunlight out. They can be either solid or slatted, with fixed or adjustable slats. Rolling shutters have a series of horizontal slats that run down along a track.

Solar screens look like standard window screens, except they block light and cut glare.
Install a durable wall cladding [MR119]

A durable wall cladding should be part of the home’s moisture management strategy. Proper installation of cladding requires a layered approach with an air space or rainscreen behind the siding so this area can dry out while also fully sealing the building envelope. Newer versions of house-wrap have textured surfaces that create a drainage plane to move water more readily behind the cladding and out to the wall assembly.

Siding properly installed over a rainscreen requires less frequent painting or staining than when installed directly over sheathing, reducing the need for refinishing. Factory pre-primed claddings are also highly efficient. Noncombustible siding, such as fiber cement, adds fire protection and often is required by building codes. This must be layered with fire-resistant screening in the air space behind the cladding to be effective.

Provide a durable and reflective roof [MR120]

Roofs are the home’s first layer of defense against the elements: temperature fluctuations, UV light, rainstorms, snow and ice, and high winds. Roofing, especially dark colored roofing, can be a source of significant unwanted heat gain. Discarded roofing material, such as asphalt shingles, is also a major source of Construction and Demolition (C&D) waste.

If adding a new roof as part of an addition or replacing an existing roof, consider environmentally friendly alternatives to conventional asphalt roofing shingles such as clay, concrete, slate tile, cool metal roofing, fiber-cement composite roofing, recycled content plastic/rubber shingles, or a green or vegetated roof (made with living plants). In general, light colored roofs offer a greener alternative to dark roofing materials since they reflect rather than absorb heat. Consider a cool metal or reflective roof with material certified by USEPA Energy Star® Reflective Roof Program. Also, look to install a highly durable, 50-year roof. Keep in mind that light colored shingles often make for a longer lasting roof since they experience less contraction and expansion than darker ones.

Cool metal roofing can achieve solar reflectance of over 70 percent, which means that less heat is transferred into the home. It also means a reduction in the urban heat island effect (the local warming due to dark-colored surfaces and buildings). Infrared emittance -- the amount of absorbed solar radiation that is re-emitted from the roof to the sky -- varies with the surface finish. For example, the emittance of painted or granular-coated metal roofing is higher than unpainted metal roofing and can be as high as 90 percent. Select cool metal roofs qualify as USEPA Energy Star® Roofing Products.

Follow standards for mechanical design [EA63]

The Air Conditioning Contractors of America (ACCA) developed standards to size heating, ventilating and air conditioning systems (HVACs) to assure maximum comfort and energy efficiency.
The ACCA also provides software that calculates heating and cooling loads. Use these calculations both before and after HVAC installation to assure effectiveness. Request load calculations from contractors to validate the overall size and design proposed. Addressing building envelope issues at the design phase can reduce the load and resulting size requirement of the home’s HVAC systems.

The ACCA Manual J - Residential Load Calculation accurately estimates heating and air conditioning loads. Manual S – Residential Heating and Cooling Equipment Selection recommends optimal heating and cooling equipment to meet loads as identified from Manual J results. Use the Manual S calculation to assure proper sizing based on the square footage and the home’s heat loss during cold weather and heat gains during warm weather. Over-sizing and improper design are major issues in HVAC installation and design. Over-sizing can compound the cause of indoor climate issues such as inconsistent temperatures from one room to another. Calibration of the sensible (or dry) cooling load and the latent (or wet) cooling load assures interactions with windows or people will be accounted for in the design.

Manual D – Residential Duct Systems provides tools for proper duct sizing and is used in conjunction with Manual J and S calculations. Correct sizing is essential to maximizing HVAC energy efficiency. A system that is too big used with a smaller duct system creates improper air flow and raises the utility bill. Proper duct design assures even air flow to each conditioned space within the home. Similar to the issues faced with an improperly or oversized HVAC unit, improper duct system design can lead to increased energy bills and a lack of comfort in the home due to an imbalance of heating or cooling in the conditioned spaces. Additional duct design attributes include well-insulated and sealed ducts that are best placed within conditioned space and with a minimum number of turns. Placement of the duct system is also essential to assure energy efficiency, promote proper functioning of the entire unit, and reduce future maintenance requirements.

Provide controls and zoning for HVAC [EA64]

The heating, ventilating and air conditioning (HVAC) system distributes air through the home via the ducting system. Assuring proper distribution across defined zones or areas of the home is another key design element and should be considered with sizing to assure an efficient system. This is especially true in determining optimal load calculations and appropriate air flow for each room. Zoning more effectively directs heating and cooling from a single HVAC system to multiple areas of the home than multiple HVAC units and avoids the added expense that comes with them.

Proper zoning controls optimal comfort and efficiency. A zone controller connects multiple thermostats to the single HVAC system and allows for cooling customization, such as focusing the cooler air in occupied spaces at optimal times. Zoning increases overall thermal comfort of a home and is particularly useful in larger homes that are poorly conditioned, such as single-zone two-story houses with a generally warmer second floor.

Use ceiling fans for natural ventilation [EA65]

Since people can tolerate higher temperatures when air is in motion, use ceiling fans in conjunction with an air conditioning system in occupied rooms. This reduces air conditioning use, thus saving electricity and money. In the summer, run ceiling fans in a counterclockwise motion. Ceiling fans can be used in the winter in a clockwise motion at low speeds to bring warm air back down into the occupied space.
Also, consider a whole house fan to avoid air conditioner usage and expense. Generally a whole house fan is used at night and turned off during the day. It moves cooler nighttime air into the house through open windows and exhausts warm air through the attic.

Another way to cool the home is with transoms in window and door designs. Designing for convection directs cool air to enter the home on the lower floors (such as through the basement) and expels warm air through upstairs windows.

Strategic location of plants and landscaping can cool (and clean) the air before it enters the home. Finally, awnings and blinds provide additional passive cooling options.

**Install programmable thermostats [EA67]**

Programmable thermostats save energy and money by allowing homeowners to set temperatures based on occupancy and to schedule setting changes. This uses heating and cooling only when needed. Programmable thermostats are especially useful if the house is empty during the work week and only fully occupied on weekends. Pre-programming and proper use of a programmable thermostat saves energy costs by minimizing heating or cooling of an empty house.

**Select high-efficiency HVAC equipment [EA66]**

Heating is the largest energy expense in most homes, accounting for 35-50 percent of annual energy bills in northern climates. Save money by reducing heating energy usage while also reducing the home’s contribution to environmental problems by upgrading to Energy Star® rated equipment as determined by the Annual Fuel Utilization Efficiency (AFUE) rating for oil and gas furnaces and boilers (and other measures as applicable to heat pumps). Energy Star® rebates apply for Energy Star® rated equipment.

The American Council for an Energy-Efficient Economy cites several considerations for assessing when it is time to replace the furnace. In particular, gas furnaces or boilers that are older than 20 years are good candidates for replacement with a high-efficiency model with the guidance of an Energy Star® certified heating contractor and heat-load calculations that the contractor provides. If it is time to replace the furnace, installing a ground-source heat pump could be an option depending on the extent of the remodeling effort; see the Ridgewood historical remodel case study at the end of this chapter for a heat pump upgrade in practice.

The efficiency of central air conditioning systems is rated by a Seasonal Energy Efficiency Ratio (SEER). SEER ratings range from 14 to 23; a higher SEER rating means a more efficient unit. Energy Star®-qualified central air conditioners have a SEER rating of greater than or equal to 14 and are significantly more efficient than standard models; as such, Energy Star® models provide for more cost savings over the life of the unit. Newer units in general have incorporated significant advances to increase efficiency. Energy Star® models also require a minimum Energy Efficiency Ratio (EER) of greater than or equal to 12 for split systems, and of greater than or equal to 11 for single-package models. While higher efficiency units often cost more initially they save on operating costs over their lifetime. A high-efficiency unit must also be designed, installed, and maintained properly to reap efficiency benefits (see [EA63]).

An effective pleated filter also contributes to savings on heating/cooling and helps prevent the introduction of pollutants into the living space. Radial pleated filter designs such as a ‘MERV 8’ provides optimal dust holding capacity, especially as compared with standard rigid fiberglass filters.
that provide little resistance against dust or bio-contaminates. Keeping the filter clean is an essential component of HVAC maintenance.

**Conduct duct tightness test**  [EA68]

**Benefits**
- Energy savings: 🍃
- Water savings: N/A
- Resource conservation: 🌱
- Air quality: 🌿

**Feasibility**
- Initial cost: $$$
- Difficulty level: TTT

Similar to a pressure test of a plumbing system, a Duct Blaster Test gauges the tightness of the ductwork. It uses a fan combined with a pressure gauge to pressurize the duct system and measure air leakage of the ductwork. The test is often performed along with a Blower Door Test as part of a Home Performance Audit to find leaks. It should be performed before and after related work to properly identify and target areas for action and to assure resolution of desired upgrades and energy and operating cost savings.

**Maintain HVAC systems**  [EA69]

**Benefits**
- Energy savings: 🍃
- Water savings: 🌊
- Resource conservation: 🌱
- Air quality: 🌿

**Feasibility**
- Initial cost: $
- Difficulty level: TT

Heating, Ventilating, and Air Conditioning (HVAC) systems can be commissioned or tested to ensure systems are operating as the manufacturers intended, e.g., refrigerant adequately charged, airtight ducts, proper room-by-room pressure and proper airflow.

HVAC systems must be properly balanced to ensure even distribution of air and need to be inspected, tested, and tuned up after installation. Zoning and other controls should also be tested to make sure they are functioning properly. To confirm functioning, have all aspects of the HVAC system commissioned. Commissioning provides documented confirmation that the HVAC systems are working as intended.

Commissioning systematically investigates, analyzes, and optimizes the performance of HVAC systems to improve their operation; maintenance ensures continued performance over time. Regular maintenance ensures that the energy efficiency upgrades remain at optimal levels as designed and are meeting the homeowner’s current needs.

To protect an investment in an HVAC upgrade and assure its efficiency over time, HVAC equipment should be tuned up annually and filters should be cleaned or be replaced on a regular basis. Energy Star® recommends tending to filters every 30 days during peak heating or cooling season. The wrong amount of refrigerant in air conditioners can also impact the functioning of the cooling unit. Proper maintenance extends the life of the HVAC system, extending the resource value of the system.

To assure regular maintenance, homeowners should consider setting up an HVAC maintenance contract for “tune-up” of your HVAC system before heating and cooling seasons to protect performance. A maintenance contract can pay for itself in energy savings and ensures that your HVAC contractor will schedule tune-ups even if you forget.

**Seal and insulate HVAC system**  [EA70]

**Benefits**
- Energy savings: 🍃
- Water savings: 🌊
- Resource conservation: 🌱
- Air quality: 🌿

**Feasibility**
- Initial cost: $$$
- Difficulty level: TTT

A house can lose over 30 percent of its heating and cooling capacity from improperly sealed ducts, especially if the ducts are located in unconditioned spaces. In the winter, hot air leaks into...
unconditioned spaces and causes the furnace to work harder. In the summer, hot attic air can leak in and increase the load on the air conditioner. A perfectly sealed operative duct system would have the same amount of air entering the return grille and leaving the supply registers, creating neutral air pressure. In contrast, leaky supply ducts create negative pressure that pulls outside air into the building. On the return side, leaks cause a suction that pulls air into the ducts, forcing more air into the home and creating a positive pressure that also overtaxes the HVAC system.

Seal all ducting with low-VOC duct mastic. The Energy Star® Thermal By Pass Checklist recommends the use of mastic, not tape, to seal ducts. Results have shown that using tape to seal ducts is ineffective as tape often frays and curls away degrading the seal. If any ductwork is in less desirable condition, or in uninsulated areas, additional insulation most likely will be required. A qualified professional can help insulate and repair ducts.

### Tips

Check references and licenses to locate a duct cleaning provider and make sure they are a certified member of the NADCA. Air duct cleaning companies must meet requirements to become a NADCA Member including having certified Air System Cleaning Specialists (ASCS) on staff.

### Caution

HVAC components can become contaminated with particles of dust, pollen or mold that can be released into the home’s living space cause allergic reactions. The homeowner should inquire about the use of biocides or chemical treatments in the duct cleaning process to make sure a service provider would not intend to use them.

Older duct systems should be inspected before cleaning to be sure that there are no asbestos-containing materials.

### Make sure ductwork is clean

**BENEFITS**

Duct cleaning refers to the cleaning of heating and cooling system components in forced air systems, including the supply and return-air ducts, registers, grilles, diffusers, heat exchangers, heating and cooling coils, drain pans, fan motor, fan housing, and the air handling unit. While clean ducts help maintain healthy indoor air quality, unless done properly, cleaning ducts can cause more indoor air problems.

If a visual inspect reveals infestation, mold or extreme debris problems, duct cleaning may be necessary. If so, be sure the service provider cleans all components of the system to avoid any recontamination that may require more serious cleaning needs. Be sure the service provider is qualified by the National Air Duct Cleaners Association (NADCA). A certified service provider uses specialized tools to dislodge dirt and other debris in ducts and vacuums them out with a high-powered vacuum cleaner. Different types of ducts require different cleaning methods; sheet metal ducts with external insulation are the easiest to clean. A Duct Blaster Test should also be performed when cleaning ducts to gauge the tightness of the ductwork. Finally, be sure to cover duct registers and openings during renovation or remodeling.

### Provide daylighting

Sunlight is a natural way to reduce energy use during the daytime hours. Homes that only require artificial lighting at night and on darker days save more electricity and are more aesthetically pleasing than ones that do not.

Windows and skylights are obvious sources of daylight, but balance daylight access with appropriate glazing and shading techniques. Poorly designed window or skylight layouts can increase summer cooling loads significantly. Awnings, louvers, and shutters can block direct sunlight and allow indirect sunlight into the building. Conversely, a well-designed scheme reduces heating loads significantly in the colder months. In the northern hemisphere, south facing windows receive the most sunlight over the course of the day. For these windows, properly sized overhangs will shade the window from direct summer heat but will allow the lower winter sunlight to filter through.

An alternative to window skylights is solar tubes. The flexible cylinders of the solar tubes draw sunlight from the roof into a ceiling fixture resembling a standard lighting fixture. They are useful in smaller interior rooms without space for a traditional skylight, such as a bathroom. Translucent panel daylight systems are another means of allowing sunlight in without producing glare and minimizing heat transfer.
Provide appropriate lighting  

Lighting consumes almost 15 percent of a household’s electricity use. Provide an appropriate mix of color-correct ambient and task lighting to improve both the quality and quantity of lighting used in the home.

Two ways of determining which lighting is appropriate for a particular use are its color temperature and its Color Rendering Index (CRI).

**Color temperature** defines the color and warmth or coolness of a light source. Color temperature is measured in degrees Kelvin (K). High Kelvin temperatures (3600–5500 K) are considered “cool” and low color temperatures (2700–3000 K) are considered “warm.” Task lighting calls for cool light that produces a higher contrast than warm light and is better for visual tasks. Warm light is recommended for living spaces. A color temperature of 2700–3600 K is generally recommended for most indoor general and task lighting applications.

The **Color Rendering Index (CRI)** is a 1-100 scale that measures how colors appear under different light sources. A light source with a CRI of 80 or higher is considered acceptable for most indoor residential applications.

Install energy-efficient lighting  

Traditional incandescent bulbs will be phased out by 2012. The technological improvements in compact fluorescent lighting (CFLs) over the past decade have made for a smooth transition. CFLs are inexpensive, last ten times as long as traditional bulbs, and use a fraction of the electricity. They also fit into standard light fixtures, allowing for their widespread use with minimal up-front cost.

Light-emitting diodes (LEDs), currently used in a variety of applications, potentially could find their way into more traditional lighting applications. Highly efficient, durable, and non-toxic, LEDs currently cost too much to warrant their widespread use. However, rapid advances in LED technology continue to push LED lighting to more practical uses.

Wherever possible, replace incandescent bulbs with greener alternatives. It is a simple and affordable way to significantly reduce home energy use.

Provide appropriate indoor lighting controls  

Lighting represents about 15 percent of household electricity usage and about 10 percent of household energy expenses. Newer lighting technologies, extensively used in commercial buildings, are now available for home use. These technologies can reduce lighting energy use in your home by over 50 percent.

Lighting controls such as dimmers, timers, and motion detectors reduce light usage by synchronizing lighting directly with living patterns. Motion detectors switch the light on when someone walks...
into a room, while light sensitive detection adjusts indoor lighting based on the changing levels of outdoor light.

High-tech lighting controls, including whole house systems that offer tie-ins to computer and security systems as well as outdoor lighting, are most effective in new construction that can be hardwired with low-voltage wiring.

**Insulate water heater** [EA80]

<table>
<thead>

<td>N/A</td>
</tr>
</tbody>
</table>

New water heaters have added interior layers of insulation that improve their energy consumption. Older water heaters are the third largest energy expense in the home, accounting for about 13 percent of the utility bill. Insulate free-standing water heater storage units for quick and inexpensive improvements in energy efficiency. Heat is lost because the temperature inside a water heater is significantly higher than the temperature of the room, especially when the water heater’s location is unconditioned. Water heater blankets and kits are available from local hardware stores and weatherization supply companies.

**Tips** [EA81]

The first six to eight feet of pipe from the water heater are the most important to insulate. Assure a snug fit around the pipes especially the elbows and angles; tight-fitting insulation is always more effective. Also Insulate cold-water pipes in areas with high summertime humidity to prevent condensation of moisture on the pipes and the associated sweating or dripping which degrades the durability of the piping.

**Building Age** [EA81]

Older homes should also consider covering cold water pipes especially those in unheated areas of the home to prevent freezing. If the hot water pipes are buried into the slabs consider re-plumbing as part of a whole house performance plan.

**Insulate hot water pipes** [EA81]

<table>

Hot water pipes usually run through unheated areas of the home, so insulating them is important to prevent heat loss and help the water heater run efficiently. Insulated hot water pipes reduce water usage by increasing the amount of time that hot water stays hot thereby reducing the need to run tepid water through the faucet. Requiring less energy to heat water also reduces water heating bills. Insulating hot water pipes on accessible pipes is an easy task. Pre-formed foam pipe insulation sleeves (available at local hardware stores) can be cut to fit snugly and snap in place on the pipes. Use a durable pipe insulation material that can withstand high temperatures over time. Cover slits and joints with vinyl duct tape to provide additional insulation.

**Utilize solar water heating** [EA101]

<table>
<thead>
<tr>

</tbody>
</table>

Solar water heating is cited as the most cost-effective renewable energy system for residential applications. Payback periods related to solar water heating differ depending on the cost of energy for heating water. In areas where electricity is used for water heating, the payback periods are shorter than for areas that use natural gas for water heating. Installing a solar water heater is a proven solution to reducing the home’s carbon footprint. Conventional electric water heaters produce about eight tons of CO₂ annually and gas water heaters about two tons of CO₂ annually.

Solar water heating can be used for domestic hot water, pool heating, and space heating needs and is in use by over a million homes in the United States. There are many types of solar water heaters. Evacuated tube solar hot water system can provide 90 percent–100 percent of domestic hot water needs. Appropriate design and climate considerations are key in the consideration of any solar
project. Care must be taken to guard against freezing of the collector and piping, and evacuated tubes for solar hot water can overheat and break if the power went out on a sunny day.

Reconfigure plumbing for efficiency

Heating the water in your house accounts for about 11 percent of your annual energy costs. One can save water and energy by redesigning plumbing efficiently. Advancements in piping materials and plumbing systems cut installation and material costs, conserve water, and save energy. Cross-linked polyethylene (PEX) piping materials have quickly earned a reputation as a durable replacement for copper because they are:

- Flexible – allowing for fewer joints and an easier (and quicker) installation
- Durable - capable of withstanding extreme temperatures and highly resistant to chemicals
- Consumer friendly – quieter than traditional piping materials and offered in color-coded PEX tubing for simple identification of cold and hot water lines.
- Energy-efficient – reduces heat loss from water in the pipe because it is a better thermal insulator than copper
- Water efficient – right-sizing capability allows for quicker hot water delivery

PEX also lends itself to home-run or parallel pipe configurations in which hot and cold pipes originate at a manifold and service individual fixtures with dedicated supply lines. Home-Run systems can be installed more quickly (because of flexible piping) than more rigid and conventional “tree” type plumbing systems. The dedicated supply lines from the manifold to the fixture – particularly in the hot water supply lines – are often smaller in diameter for a Home-Run system, so less water goes down the drain while waiting for hot water at the fixture. Finally, Home-Run systems operate much like an electrical system breaker box, allowing homeowners to easily turn off the water for repairs or maintenance.

Select a high-efficiency clothes washer

Clothes washers are responsible for about 22 percent of household water consumption or about 13,000 gallons of water each year. Today’s energy-efficient washers reduce water use and energy bills.

Replace a clothes washer when 1) a repair will cost more than half the price of a comparably equipped new appliance, and 2) a washer is more than seven years old. If you are in the market for a new clothes washer consider the following:

- In selecting a washer load capacity, consider the household’s largest routine load – larger capacity means fewer loads, saving time and energy
- Front-loaders use less energy and water, are usually gentler on clothes, and have faster spin speeds that drain more water out of laundry than regular top-loaders do thus shortening drying times and energy use
- Look for washers with the Energy Star® label

Front-loading washers are more expensive than top-loading washers, but in New Jersey rebates are available for units that meet Tier 3 Energy Star® standards which require a Modified Energy Factor (MEF) of 2.2 or higher and a maximum Water Factor (WF) of 4.4. There is no certification

Tips

Consumer Report’s Washer Tips:
1. Keep wash temperatures low. Reserve hot water for very special stains, like oil, that respond best to hot water, or for allergy-proofing bed linens. Also consider cold water detergents.
2. Wash full loads.
3. Use your washer’s fastest spin speed. The more water your washer extracts from clothing at the end of the cycle, the less energy your dryer will need to dry the clothes

Incentive

New Jersey Energy Star® Rebates
www.njcleanenergy.com/
for dryers, but a unit with a moisture sensor that turns off automatically when clothes are dry saves money and energy.

Select an energy-efficient refrigerator

Refrigerators consume more electricity than any major kitchen appliance. Energy efficient refrigerators like Energy Star® models are about 40 percent more efficient than refrigerators built before 2001, and 50 percent more efficient than those built before 1993. If an existing refrigerator is more than 10 years old, consider upgrading to a refrigerator that meets or exceed Energy Star® standards as a new refrigerator with an Energy Star® label uses at least 20 percent less energy than one required by current federal standards.

Size, options and freezer compartment configurations affect energy use. A larger unit may be Energy Star® certified, but a smaller unit may still use less energy, so choose the smallest refrigerator that appropriately meets household needs. Features (such as water dispensers) use energy, so fewer features mean both greater energy efficiency and a lower likelihood of repairs. Top freezer models are generally more energy efficient than side-by-side models. Leave room around the unit for proper air flow around the cooling coils to ensure peak efficiency. Maintaining the unit is also important.

Choose an energy-efficient dishwasher

Most dishwasher energy use goes toward heating water, however, today’s high-efficiency dishwashers use as little as three gallons of water thanks to sensors, high-efficiency pumps, and improved filtration. The expected life of a dishwasher is 9-12 years, and the payback period for a new dishwasher is long, but studies suggest it is more sensible to replace a dishwasher that is more than six years old rather than pay for repairs. Look for dishwashers that carry the Energy Star® label, which are over 40 percent more energy-efficient than the minimum government standards.

Install energy-efficient cooking appliances

Cooking itself does not contribute significantly to overall home energy use, but preheating does, making it sensible to invest in an energy-efficient model. When shopping for new cooking appliances or remodeling the kitchen, consider making a fuel switch since running gas pipes, vents, and electrical connections will influence the layout of the kitchen. Consider cooking preferences and local gas and electric rates. If another appliance such as a furnace, clothes dryer, or water heater is also on a switch list, take this into consideration when you look at placement and installation costs.

In general, electric ranges and ovens are more efficient than gas units. The most efficient ovens are convection ovens that cook by circulating hot air around the food, using only one-third as much energy to operate as conventional ovens. They produce further savings through reduced cooking times because the food is more evenly exposed to heat. Among electric ranges, induction models may cost more but they are also the most efficient.
In terms of gas units, look for electronic or thermal igniters instead of standing pilot lights. For smaller meals, consider using a microwave oven or a toaster oven that require less energy than a large oven. Self-cleaning gas or electric ovens are more efficient because they have more insulation than non-self cleaning models.

Select energy-efficient office equipment [EA99]

Today there are about 18 million home-based business owners and 24 million telecommuters. Working from home eliminates commute times and transportation-related emissions, but it contributes to higher electricity bills to power office equipment and lighting. In fact, small electronic devices alone account for 16 percent of an average home’s energy bill. Office equipment that has earned the Energy Star® label uses less energy to perform regular tasks and automatically enter a low-power mode when not in use, thereby reducing phantom loads. Up to 75 percent of the electricity these units consume occurs while these devices are turned off. When buying new office equipment, consider both the standby and the operating power consumption.

Energy Star® ratings are available for computers, monitors, printers, scanners, copiers, fax machines, multi-function devices (machines that combine printing, scanning, and faxing), lighting, cordless phones, answering machines, audio equipment, and room air conditioners.

Consider on-site renewable energy [EA102]

Ongoing advances in solar and geothermal technologies coupled with broader government financial incentives have made on-site renewable energy increasingly more feasible for the homeowner. Providing some or all of the home’s energy from on-site renewable sources is an excellent way to not only significantly reduce utility bills, but also decrease one’s reliance on and consumption of traditional fossil fuel energy sources.

Due to the increasing number of incentives for solar equipment, a homeowner can install a photovoltaic array with smaller up-front costs and a quicker payback period. New Jersey maintains a Solar Renewable Energy Certificate program that allows participants to receive sellable credits for the energy that they produce; each time a system generates 1000 kWh of electricity, a SREC credit is issued to the program participant. Also, all equipment related to solar energy—including passive solar equipment—is eligible for sales tax exemption in the state.

Another option for on-site energy production is the implementation of a solar water heating system. Solar water heaters can be either passive or active; passive systems are generally less expensive but not as efficient as active ones. In New Jersey, a solar water heater would need to be used in conjunction with a traditional water heating system for cloudy days and winter months.

Geothermal technologies take advantage of relatively constant underground temperatures by pumping cooler air in the summer and warmer air in the winter to the surface. One of the more common applications of geothermal technology for homeowners is ground source heat pumps (GSHPs). Properly designed and installed GSHPs can provide efficient, clean, and renewable heating and cooling for homes. The U.S. Department of Energy calculates a payback period for individual geothermal systems of five to ten years from decreased energy costs. The Resources section contains a link to the International Ground Source Heat Pump Association’s website, which maintains a database of accredited geothermal heat pump installers.
Building Envelope
Conduct a Home Performance Audit and diagnostic tests [IPD2, EA51-54]

Location of Project: Yardley, Pa  
Homeowners: Parkland Properties, LP, Thomas G Wells, Member  
Interior Designer: Emily K. Buehrle, EKB Designs  
General Contractor: Thomas G Wells Construction, L.L.C.  
Area Affected: 3200 sq feet

Overview and Scope
This two-stage home renovation increases energy efficiency, improves indoor air quality, and utilizes sustainable building products. The first stage was a remodel of the kitchen, increasing its size from 123 square feet to 180 square feet. The second stage began with a comprehensive Energy Audit of the building envelope followed by remediation of air infiltration and insulation deficiencies, replacement of the existing oil furnace with a heat pump, and a post-remediation Energy Audit. The overall goal of the contractor was to make the interior space comfortable and visually appealing while ensuring easy maintenance and energy efficiency.

Design Approach
The house is a rental property that the owners intend to rent well into the foreseeable future. This will enable monitoring of energy consumption and equipment durability over an extended period. The contractor saw this as an opportunity to try out various sustainable building products and energy efficiency strategies. He looked at the products needed for the project (i.e., new counter tops) and evaluated various sustainable options that fit the criteria. He also used this opportunity to evaluate the feasibility of various energy upgrades, such as air sealing and insulating knee walls in crawl spaces. The interior designer, Emily Buehrle, has a strong background in space planning and sustainable building products. She assisted the homeowners to meet their goals of interior features, colors, and textures that would resonate with the home’s future occupants.

Team and Process
Tom Wells and his crew did the majority of the framing, finishing, window installation, cabinetry installation, and painting, while various other parts of the project were subcontracted. Tom was the leader in designing the green aspects of this project, relying on input from Wes Carver Electrical Contractors and Rob Taurino of JA Smith Heating and Air Conditioning. Ted Inoue was invaluable as the energy auditor and system evaluator.

Finance
The total cost of the renovations without the standard contractor mark-up was approximately $81,000. This overall cost did not seem out of proportion to other traditional kitchen remodeling projects done by the contractor. For this project, budgeting generally came secondary to the project goals; more importantly, the team wanted to demonstrate the value of techniques and products of which the average contractor and homeowner may not be aware. These included bamboo cabinetry, recycled glass countertops, low-VOC paints, spray foam insulation, and a heat pump to replace the oil furnace. The roof needed to be replaced unexpectedly due to leaky skylights; an asphalt roof was chosen instead of a metal roof for budget reasons. After the work was performed, the entire interior of the house was repainted.

First cost savings were not achieved by utilizing the green products, but are realized when factoring in the reduced energy consumption costs, increased comfort level, and otential increase in resale value of the house. The contractor also benefited from increased focus on his company by potential clients interested in green remodeling.

Lessons and Trade-offs
The major surprise came during the Energy Audit, which highlighted the many parts of the house that had air infiltration and insulation issues. The contractor believes that making the house as “tight” as possible is the most important aspect of the green remodel. The biggest trade-offs came from the unexpected roof replacement.

“The kitchen remodel is the most appealing and dramatic change to the house, but I am personally most excited about the energy efficiency package we installed. We are looking forward to monitoring the energy usage per square foot to see how it compares to homes of similar size.”  
- Tom Wells
List of Green Strategies

Energy Conservation

• Replaced old windows with low-E windows
• Removed trim from the windows and installed minimal expanding foam in the gap around the windows
• Replaced oil furnace with high-efficiency heat pump
• Installed spray foam insulation in open walls and ceilings in the kitchen, crawl space, the basement band joist, and part of the roof sheathing
• Installed dense pack cellulose in the exterior walls and attic
• Installed fiberglass batts covered with rigid foam board in second floor knee walls
• Caulked the baseboards to the hard wood floor
• Replaced the light bulbs with CFLs in the bedrooms
• Installed CFL recessed lights and high-efficiency light fixtures with insulated boxes in the kitchen, dining room, and family room
• Installed LED under-cabinet lighting
• Put mastic on the HVAC ductwork seams

Water Conservation

• Installed low-flow showerheads
• Utilized a kitchen faucet with a filtered water option

Indoor Air Quality

• Used low-VOC interior wall paints
• Used waterborne hardwood floor finishes

Sustainable Materials

• Installed recycled glass countertops and bamboo cabinetry with no added formaldehyde in the kitchen
• Installed a natural linoleum kitchen floor
• Used natural earth plaster and cork sustainable flooring in the mudroom
• Installed 50-year fiberglass architectural roof shingles

The bright yellow shows the hotter warm floor and insulation. The darker spots reveal the leaks from under the baseboard and the loss of heat through the studs.
Location of Project: Mill Hill Historic District, Trenton, New Jersey
Homeowners: John Hatch, David Henderson
Architect: W. David Henderson, R.A., HHG Development, LLC; John D. S. Hatch, AIA; Clarke Caton Hintz
General Contractor: Atlantis Historic Properties
Area Affected: 3,000 sq. ft.

Overview and Scope
The project is the major renovation of an 1887 row house in Trenton’s Mill Hill Historic District. When purchased, the house had been vacant for a number of years and was in need of major rehabilitation, including structural repairs, window replacement, all new systems (electrical, plumbing, and HVAC), repairs to damaged walls, replacement of roof, and installation of insulation.

Design Approach
In keeping with their commitment to green practices the design team decided to implement as many sustainable strategies as possible while still preserving and restoring the historic character of the house. Since the house is located in a designated local, state, and national historic district, the local historic preservation commission reviewed certain work. This included the exterior windows and the installation of the solar panels. The new windows have insulated glass and are very efficient, but match the original arched windows quite closely. The Landmarks Commission approved them. Since the solar panels are located on a roof not visible from the street, the installation was not an issue.

Team and Process
The homeowners and the designers are one and the same, so that relationship was easy to manage. Making this project as green as possible meant reaching out to various contractors and suppliers to get ideas and products for how to improve the efficiency and sustainability of the house.

Finance
Based on prior utility bills and estimated usage, the house is at least 25 percent more efficient so energy costs are significantly lower. In addition, the solar panels provide 75 percent of the electricity that is typically used. When more power is produced than used, it is sold back to PSE&G. Most of the electrical bills are only $5! In addition, the homeowner received various green power incentives through the state and federal governments, which also helped to reduce up-front costs. This has made the payback for the solar panels very quick.

Since the house needed such major renovations, it was a question of choosing the most energy- and water-efficient items throughout the remodeling process. These may have cost slightly more than the alternatives, but were considered in the financing for the overall project.

Lessons and Trade-offs
The project team and homeowner were surprised at the affordability of the green strategies. If they had to do it all over again, they would go even further with the sustainable and energy-efficient strategies, even if they cost more. In the future, the payback will only get shorter!

“Making projects energy and water efficient while using sustainably produced products is only getting easier with time. In addition, it’s getting more and more cost effective. While people don’t normally associate historic preservation with sustainable design, reusing existing structures is actually one of the most sustainable actions that anyone can take. There is a tremendous amount of energy and carbon stored in the historic building’s structure, energy that would be wasted if the building were demolished and rebuilt. The greenest home is the one that’s already built!”

- John D. S. Hatch
List of Green Strategies

Energy Conservation

• Installed photovoltaics provide more than 75 percent of the electrical requirements
• Installed high-efficiency heat pump: 17 SEER
• Purchased new combination washer and condensing dryer that utilizes a closed system to remove moisture from clothes, saving energy and eliminating the need for outside venting
• Utilized Energy Star® appliances
• Installed R15 insulation added to most walls, R30 to roof; as the original walls and roof had no insulation
• Replaced all light bulbs, inside and out, with color corrected compact fluorescent
• Installed solar powered attic fan keeps air flowing in the attic to reduce condensation, heat build-up and energy costs
• Replaced or restored most of the original windows with historically accurate windows with insulated glass and low-air infiltration

Water Conservation

• Used ultra low flow toilets: 1 gallon per flush

Sustainable Materials

• Utilized reuse of most interior materials. Wood floors and plaster walls were kept wherever possible. Reused two claw foot tubs; wood moldings were either kept in place, or, if reconfiguring the space, were removed and reused
• Use materials that are historically appropriate (wood windows and doors, for instance) and are also sustainable
Location of Project: Princeton, New Jersey
Homeowners: Janet Black
Energy Auditor: GreenStreet Energies
General Contractor: GreenStreet Construction
Area Affected: 2,000 sq. ft.

Overview and Scope
This weatherization and energy upgrade to a two-story, late 19th/early 20th century colonial-style home included a comprehensive Home Performance Audit and implementation of energy-efficient recommendations by GreenStreet Energies, a home performance consulting service of GreenStreet Construction. An audit checklist and thermal-imaging scans were used to reveal leaks and sources of air infiltration and energy loss in the home. The tests revealed opportunities to add insulation and to seal up drafty areas around the windows and doors with weather stripping. Spray polyurethane foam was added under the first floor in between the basement ceiling beams, where no insulation or subfloor existed. GreenStreet also installed storm doors, storm windows, and door sweeps.

Design Approach
The homeowner, Janet Black, was introduced to GreenStreet Construction while attending a presentation they made at Design Within Reach, an interior design store located in Princeton, New Jersey. She approached GreenStreet and expressed her interests in greening her home. Working with the homeowner, GreenStreet carried out the Energy Audit and upgrades.

Team and Process
GreenStreet Energies provided a detailed Energy Audit report and recommended upgrades to correct the deficiencies that the audit uncovered. They subsequently were hired to perform all the energy work except for the installation of the spray foam insulation, which was performed by an insulation company. The whole project was completed in less than two months.

Finance
The total cost for the Home Performance Audit including energy work was about $5000, with an estimated payback period of three to four years. The project was completed very recently so the homeowner currently is waiting to see how the energy bills will be affected. The homeowner plans to reinvest her energy savings into future energy upgrades such as installing storm windows on the remaining second floor windows.

Lessons and Trade-offs
The antique floor had gaps between the floorboards, without any subfloor underneath. This presented a problem as the spray polyurethane foam could possibly foam up out of the basement into the living area. GreenStreet fixed the problem by doing a little prep work from the basement side to seal up most of the larger gaps so that the expanding foam insulation didn’t come up through the floor.

“Every home is different. This brings a need for a collaborative between GreenStreet and the client in order to take full advantage of all the tools and information available to produce exactly what the client is looking for.

In the case of Janet Black’s home, we found a situation unfortunately common in older houses - a beautiful antique floor with small gaps in between the floorboards was the only thing separating her first floor living space from her 40-45 degree basement. We realized that assumptions cannot be made about previous construction, whether it is as obvious and visible as this situation or something hidden deep within the construction of the house.”

- Rees Keck, GreenStreet Energies

Added insulation in basement (before barrier)
**List of Green Strategies**

**Energy Conservation**
- Installed spray foam insulation in areas lacking insulation, such as the basement ceiling*
- Added storm windows and weather stripping to all doors and windows to reduce air leakage
- Added storm doors and door sweeps to reduce drafts around existing entrances

**Indoor Air Quality**
- Installed formaldehyde-free spray foam insulation*
- Used only non-toxic caulking and weather stripping materials

**Resource Conservation**
- Added storm windows and doors instead of replacing existing windows and doors, increasing their durability by adding a layer of protection from the elements

*Spray foam materials installed in walls or ceilings may present a fire hazard unless protected by an approved, fire-resistant thermal barrier with a finish rating of not less than 15 minutes as required by building codes. Rim joints/ header areas in accordance with the IRC and IBC may not require additional protection. Foam plastic must also be protected against ignition by code-approved materials in attics and crawl spaces. See relevant Building Codes and www.iccsafe.org for more information.

---

*Spray foam insulation in basement (before thermal barrier is added)*

*Storm door installed to provide added protection*
**Location of Project:** Trenton, New Jersey

**Developer:** Isles Inc. and Tara Construction Management Corp.

**Architect:** Frank Russo, Shapiro Petrauskas Gelber

**Contractor:** Omega Corporation

**Green Design Consultants:** Lyle Rawlings, Advanced Solar Products, Inc. and Andy Shapiro, Vermont Energy Investment Corporation

**Area Affected:** 2 semi-detached, 1700 sq. ft. units

---

**Overview and Scope**

In an area of Trenton, New Jersey where many of the dwellings are vacant or in disrepair, the 22 semi-detached units of the Bellevue Court project have newly renovated interiors restoring façades to their original grandeur. Part of the larger project, the dwellings at 233-235 Bellevue Court have green technologies behind their traditional brick façades.

Spearheaded by the City of Trenton and developed by Isles Inc. and Tara Construction Management Corp, these two “microload” homes are projected to use 60 percent less energy than a code compliant home and 30 percent less energy than their Energy Star® neighbors.

---

**Design Approach**

The two 1700 square foot units have three bedrooms and two and one half baths. Sustainable and recycled materials were incorporated throughout the homes. To help provide exceptional air quality in these airtight homes, mechanical ventilation is provided using a heat recovery ventilator (HRV). The exhaust vents from each bathroom and kitchen are ducted to the HRV while fresh air from the HRV feeds into the return plenum of the furnace.

The real benefit in these houses is the dramatic reduction of their heating and cooling loads and the ability of these homes to meet a substantial part of those loads with renewable energy. Heating and cooling losses were reduced through the building envelope with highly insulated walls and windows and air sealing. Custom designed overhangs on the south wall of the “microload” homes block the high summer sun and allow for passive solar heating during the winter. The window glass was selected to allow solar heat to enter in winter. As a passive cooling strategy, a skylight with a manually operated crank was placed over the central stair to allow for warm inside air to move up and out of the house in summer. This also provides daylight in the area.

A 2.5 kW photovoltaic array on the roof is projected to offset close to 70 percent of the electric loads in the house. The system will be net metered, allowing unneeded solar-produced electricity to be sold back to the utility.

---

**Team and Process**

Responding to a need for affordable housing and eager to save the architecturally unique homes on Bellevue Court, the City of Trenton committed to bringing back the block. Isles Inc. and Tara Construction Management Corp were selected as the nonprofit/for-profit partnership for the project.

**Finance**

For the entire 22-unit Bellevue project, the development costs (including property acquisition, construction, professional services, developer’s fees, and other costs) totaled $4.2 million. The units were donated by the City of Trenton, along with a $1 million grant. Additional funding for the project was provided through state and federal grant money.

**Lessons and Trade-offs**

Looking strictly at the energy usage of the two solar homes, the buildings are performing less efficiently than modeled. A few observations reveal interesting lessons.

Homeowner consumption is a major factor in the energy efficiency equation. Both of the owners are using electric heaters on the first floor, both have 240 kWh/year freezers in the basement and both have multiple televisions and other electronics with significant plug loads. One homeowner is utilizing an electric fireplace for heat that is placed near the home’s thermostat. In addition, one of the homeowners always has shades drawn on the south facade, which was designed for direct solar gain “sun tempering.” According to the homeowner, this primarily is for security and privacy reasons.

Also, a number of systems and certain features where not properly installed or balanced. Finally, the PV system on one home is being shaded by an adjacent home, creating less than optimum conditions for electric generation. These situations confirm the need for residential commissioning, particularly for complex integrated technologies found in high performance homes.

“Cellulose insulation was a change from the construction contractor’s normal practices, but they were sold on the acoustic performance of the product. “When you close the outside door in these houses, it’s like being in a sound-proof room.”

- Omega Corporation
List of Green Strategies

**Energy Conservation**
- Installed highly efficient insulation in walls and ceilings
- Chose fiberglass frame double glazed low-E windows
- Carefully sealed all rough openings and basement ceilings
- Installed high-efficiency HVAC and water heating equipment
- Installed Energy Star® appliances throughout
- Installed a 2.5 kW rooftop photovoltaic array to provide a portion of the building’s electricity needs

**Water Conservation**
- Installed dual-flush low water use toilets, low-flow showerheads, and low-flow faucets
- Created a rainwater collection system for gardening
- Planted drought-proof native plantings and grasses

**Indoor Air Quality**
- Used zero and low-VOC paints, caulks, finishes, and adhesives
- Purchased formaldehyde-free plywood kitchen cabinets
- Utilized a track-off mat system at the entryway
- Installed wood flooring and ceramic tile instead of carpeting
- Properly vented all occupied rooms
- Provided exhaust for all high-moisture areas

**Sustainable Materials**
- Reused and recycled many materials during construction
- Reused brick from the site for pervious paving
- Utilized recycled content plastic/wood lumber for porches and decks
Green Products and Services

Introduction

The purpose of the Green Products and Services is to help homeowners navigate the market with some helpful tips on what to look for when shopping for a particular green home remodeling project. The Guide is organized by building system and lists the general products and services that pertain to remodeling tasks within that system. It includes features and applicable certifications to look for, as well as web links to more information on that product or service. Each item in the Guide also refers to the related REGREEN strategy IDs.

Please note that the New Jersey Green Home Remodeling Guidelines Version 1.0 do not endorse any particular brand or company. It is not the function of the Green Product and Service Guide to direct the consumer to a specific product, but rather to provide a resource to seek out an appropriate manufacturer or service provider to handle remodeling needs.

With the ever-increasing number of green products and services coming into the home remodeling market, finding the appropriate ones can be a challenge. Some manufacturers market products as “green” when in reality they are only marginally better for the environment or whose green features are neutralized by other aspects of their manufacturing or composition. This phenomenon is referred to as “greenwashing” and calls on consumers to seek out references and ensure the true extent of green value.

Product Certification Programs

That being said, there are several leading green product standards and certification programs that can help consumers identify products that meet predefined green criteria. The leading green product standards and programs include:

- Energy Star® - identifies efficient products that reliably deliver energy savings and environmental benefits
- WaterSense – identifies high performing, water efficient products and practices
- Cradle to Cradle - certifies products based on lifecycle of materials used to construct a product and the overall lifecycle of the product
- GreenGuard® Certification Program - certifies products and processes for their low chemical emissions and low toxicity
- Green Seal® - certifies products and practices for their low toxicity and overall environmental impact
- GreenSpec Directory - a published resource on environmentally preferable products
- Forest Stewardship Council (FSC)- certifies wood products coming from forests managed to meet social economic and ecological needs
- Sustainable Forestry Initiative (SFI) - certifies wood products coming from well-managed forests and responsible procurement practices
- National Fenestration Rating Council® (NFRC) - a non-profit organization that administers the only uniform, independent rating and labeling system for the energy performance of windows, doors, skylights, and attachment products

For more information on various certification programs currently in use by architects and designers see:
- the ecolibrary™matrix - www.thegreenstandard.org/documents/GGNCO9_EcoLibCert.pdf
- Gaia Product Profile developed by The Green Standard™ - www.thegreenstandard.org/gaia.html

Two other reputable sources for green products and services are:
- Green Building Advisor that lists products from the GreenSpec Guide to Residential Building Materials www.greenbuildingadvisor.com/
Product Standards for GreenSpec

1. Products Made with Salvaged, Recycled, or Agricultural Waste Content
   a. Salvaged products
   b. Products with post-consumer recycled content
   c. Products with pre-consumer recycled content
   d. Products made with agricultural crop waste material

2. Products That Conserve Natural Resources
   a. Products that reduce material use
   b. Products with exceptional durability or low maintenance requirements
   c. Certified wood products
   d. Rapidly renewable products

3. Products That Avoid Toxic or Other Emissions
   a. Natural or minimally processed products
   b. Alternatives to ozone-depleting substances
   c. Alternatives to hazardous products
   d. Products that reduce or eliminate pesticide treatments
   e. Products that reduce stormwater pollution
   f. Products that reduce impacts from construction or demolition activities
   g. Products that reduce pollution or waste from operations

4. Products That Save Energy or Water
   a. Building components that reduce heating and cooling loads
   b. Equipment that conserves energy and manages loads
   c. Renewable energy and fuel cell equipment
   d. Fixtures and equipment that conserve water

5. Products That Contribute to a Safe, Healthy Built Environment
   a. Products that do not release significant pollutants into the building
   b. Products that block the introduction, development, or spread of indoor contaminants
   c. Products that remove indoor pollutants
   d. Products that warn occupants of health hazards in the building
   e. Products that improve light quality
   f. Products that help noise control
   g. Products that enhance community well-being

50-year roof 50 year roofs are built with durable materials such as fiber-cement that enable them to last up to 50 years.

The Air Conditioning Contractors of America’s (ACCA) Manual S Manual S provides information on selecting the appropriate heating and cooling equipment of a home based on the calculations derived from the formulas in Manual J.

The Air Conditioning Contractors of America’s (ACCA) Manual D Manual D is a guide to designing residential duct systems

The Air Conditioning Contractors of America’s (ACCA) Manual J Manual J describes how to calculate the heating and cooling loads of a home.

ambient lighting Ambient lighting uses “warm” lighting sources with a color temperature between 2700-3000K that are more flattering to skin tones and clothing, recommended for living spaces.

asbestos Asbestos is the name given to a number of naturally occurring, fibrous silicate minerals mined for their useful properties such as thermal insulation, chemical and thermal stability, and high tensile strength. Asbestos is commonly used as an acoustic insulator, and in thermal insulation, fire proofing and other building materials. Many products in use today contain asbestos.

awning An awning is a constructed frame covered in a fabric that extends from an existing structure (usually the side of a house) to provide protection from the sun and rain.

backdrafting Backdrafting refers to the process in which a home becomes depressurized from air escaping to the outside and is replaced with air entering from the exterior that may contain combustion products including carbon monoxide.

baffles Baffles are devices used to control movement of light, fluids, wind, and other forces.

biocide Biocides are chemicals used to destroy living organisms. They are typically selective and can be used agriculturally as pesticides or in other industries to control the infestation and growth of unwanted organisms.

Blower Door Test The Blower Door Test measures the leakiness of the house or its air infiltration and helps a homeowner prioritize problem areas. This test uses pressure differences created by air flow via a calibrated fan that mounts on the frame of an existing door and pulls air out of the house, lowering the inside air pressure. As higher pressure outside air travels in through unsealed cracks and openings, tools like a smoke pencil can detect these air leaks as part of a visual inspection process.

borate Borates are boron-containing, naturally-occurring minerals. Common commercial applications of borates include wood treatment, detergent additive, and plant fertilizer.

building envelope The building envelope of a structure separates its interior from the exterior.

carbon dioxide (CO₂) Carbon Dioxide (CO₂) is a gas byproduct of the burning of fossil fuels and other forms of combustion.

carbon monoxide (CO) Carbon Monoxide is a toxic gas byproduct of combustion that is both odorless and colorless. Sources of its production include wood stoves, fireplaces, gas stoves, and furnaces among others.

casement windows Casement windows are hinged and open like doors with a crank.

cellulose Cellulose fibers from recycled newsprint can be applied as a form of insulation that is flame, mold, and pest resistant, provides thermal and sound insulation, and resists settling.

Cellulose insulation Cellulose fibers from recycled newsprint can be applied as a form of insulation that is flame, mold, and pest resistant, provides thermal and sound insulation, and resists settling.

CFC sealant Chlorofluorocarbon (CFC) sealants and other CFC products cause ozone depletion.

chase Chases are grooves cut into walls to receive pipes, cables, or ducts.

cladding Wall cladding is a nonstructural material used as the exterior covering for the walls of a building.

Color Rendering Index (CRI) The Color Rendering Index (CRI) is a 1-100 scale that measures how colors appear under different light sources. A light source with a CRI of 80 or higher is considered acceptable for most indoor residential applications.

color temperature Color Temperature defines the color and warmness or coolness of a light source. Color temperature is measured in Kelvin (K) temperature. Contrary to what is expected, higher Kelvin temperatures (3600–5500 K) are considered cool and lower color temperatures (2700–3000 K) are considered warm.

• A color temperature of 2700–3600 K is generally recommended for indoor general and task lighting.

• Task lighting calls for cool light that produces a higher contrast and is better for visual tasks.

• Warm light is more flattering to skin tones and clothing and is recommended for living spaces.

combustion Combustion is the chemical process of the release of gasses in the process of burning a fuel.

combustion appliances Combustion appliances refers to appliances such as stoves, water heaters, and clothes dryers that burn fuels. It is important to make sure that these appliances work correctly and are properly ventilated to prevent carbon monoxide, a byproduct of combustion, from entering the home.

commissioning Commissioning ensures that a home’s mechanical systems have met their design intent, operate and interact optimally.

Compact Fluorescent Lights (CFLs) Compact fluorescent lights are the miniature fluorescent lights that can screw into standard light fixtures that conventionally use incandescent bulbs. CFLs are more energy-efficient and durable than incandescent bulbs.

cool metal roofing Cool metal roofing is made from metals such as copper that is used to reflect sunlight and reduce the amount of heat that is transferred into a building.

cooling load Cooling load refers to the amount of heat that is to be removed from a space by a cooling system.
cross-linked polyethylene (PEX) Cross-linked polyethylene is a plastic often used for water supply piping that is flexible, resistant to scale and chlorine, doesn't corrode, is faster to install, and has fewer connections and fittings than does metal piping or rigid plastic piping such as PVC, CPVC, and ABS.

damper Dampers are adjustable plates located in the flue of a fireplace that prevent heat from escaping when it is not in use.

deciduous trees Deciduous trees are species that shed their leaves for part of the year.

diffuser Diffusers are circular, square or rectangular air distribution outlets which are usually located in the ceiling. They are comprised of deflecting blades which discharge supply air in various directions. Diffusers are designed to mix the conditioned air entering the space with the air already contained in the space.

disposable respirators Disposable respirators or filtering facepieces can be made of cloth or paper and are designed to clean the air as you breathe it to prevent you from inhaling irritating substances.

door sweep Door sweeps are hardware that attach to the bottom of a door to reduce draft.

double-hung window(s) Double-hung windows have two vertically sliding sashes, each closing a different part of the window.

double-pane window(s) Double-pane windows consist of two pieces of glass separated by an air space. The air space allows for less heat transfer between the interior and the exterior of the home reducing heating and cooling loads.

drain pans Drain pans provide a basin to catch any fluids leaking from a piece of equipment such as a clothes washer.

Duct Blaster Test A Duct Blaster Test utilizes a fan and a pressure gauge to measure the amount of air escaping from the ductwork of a home by pressurizing the system.

duct cleaning Refers to the cleaning of heating and cooling system components in forced air systems, including the supply and return-air ducts, registers, grilles, diffusers, heat exchangers, heating and cooling coils, drain pans, fan motor, fan housing, and the air handling unit.

duct mastic Duct mastic is a sealant used to reduce air leakage in duct systems. Its flexibility enables it to contract and expand.

duct squeezing Duct squeezing refers to the use of under-sized ducts in an HVAC system in tight spaces that accelerates the air flow creating excessive noise and increases the system's operating costs.

ducting system Ducting systems are networks of ducts or formed sheet metal that direct the flow of air from central HVAC units.

energy performance rating Energy performance ratings indicate the potential for heat transfer and sunlight transmittance of windows, doors, and skylights.

Energy Star® for Homes Typically 20-30 percent more efficient than standard homes, Energy Star qualified homes must meet certain criterion including energy saving features.

Energy Star® Thermal Bypass Checklist (TBC) The Energy Star® Thermal Bypass Checklist consists of guidelines for a home inspection that may reveal any opportunities for energy efficiency improvements.

Extruded Polystyrene (XPS) Extruded polystyrene is a plastic foam insulating material that is resistant to moisture, rot, mold, and corrosion.

fiber cement Fiber cement siding is composed of sand, cement, and cellulose that make it more durable than wood, is termite- and water-resistant, and non-combustible.

fiber-cement composite roofing Fiber-cement composite roofing is made of sand, cement, wood fiber and clay. It is recyclable, fire-proof, and durable, lasting up to 50 years.

flame spread rating Flame spread ratings (FSRs) are used to evaluate the surface burning characteristics of building materials including ignition temperature, smoke toxicity, and flame-spread. Building materials are compared to the FSR scale where inorganic reinforced cement board is 0 and red oak is 100.

flashing Any piece of material, usually metal or plastic, installed to prevent water from penetrating the structure.

foam sheathing Foam sheathing includes expanded polystyrene (EPS), Extruded Polystyrene (XPS), and Polysiocyanurate (PIR). These foam insulation materials are used for applications such as controlling heat flow, airflow, rain penetration, water vapor flow, and condensation.

formaldehyde Formaldehyde is a chemical compound used in products including paper towels, photographic film, glues, and inks among others. It is important to avoid products containing formaldehyde whenever possible as they off-gas potentially hazardous pollutants.

formaldehyde-free Formaldehyde-free products don't contain any formaldehyde. Formaldehyde-free products should be avoided whenever possible.

glazing Window glazings are compounds applied to glass to reduce the amount of heat transfer between the interior and the exterior of a building and/or the ultra-violet (UV) light passing that passes through it.

grille Grilles are vent covers that are normally used on air return ducts. Grilles do not have a pre-attached damper. Louver assemblies can be used with grilles so that the grilles can be used on forced air ducts and still provide airflow control.

gypsum Gypsum is a mineral found in sedimentary rock formations in a crystalline form known as calcium sulfate dihydrate. It is typically used in gypsum board that consists of a non-combustible core.

gypsum board Gypsum board or drywall is used in various paneling applications that consists of a paper-faced non-combustible gypsum core.

hard wire Hard wiring refers to the use of cables or electric wire to connect electronic components.
heat exchanger(s) Commonly used in space heating, refrigeration, air conditioning, and other applications, heat exchangers are devices built for efficient heat transfer from one medium to another.

heat pump system Heat pumps use electricity to move heat from a cool space into a warm, making the cool space cooler and the warm space warmer. During the heating season, heat pumps move heat from the cool outdoors into your warm house; during the cooling season, heat pumps move heat from your cool house into the warm outdoors. Because they move heat rather than generate heat, heat pumps can provide up to 4 times the amount of energy they consume.

heating and cooling coils The heating and cooling coils of an appliance or piece of machinery converts electricity into heat energy.

heating load Heating load refers to the amount of heat it takes to maintain the temperature of an indoor space.

Heating, Ventilation, and Air Conditioning (HVAC) Systems Heating, Ventilating, and Air Conditioning systems process and supply air through ductwork helping to regulate humidity and temperature in buildings to provide safe and healthy conditions.

HEPA filtered air scrubbers High efficiency particulate air or HEPA air filters are a type of high-efficiency air filter that remove at least 99.97% of airborne particles down to a size of 0.3 micrometers (µm) in diameter.

HEPA vacuum High efficiency particulate air or HEPA filters are a type of high-efficiency air filter that remove at least 99.97% of airborne particles 0.3 micrometers (µm) in diameter. HEPA filter used in vacuum cleaners trap the fine particles (such as pollen and dust mite feces) which trigger allergy and asthma symptoms.

high-density fiberglass batts High-density fiberglass batts are insulation with higher R-values (a measure of resistance to heat flow) than other fiberglass batts. These materials are considered to be less irritating and don’t require a chemical binder for securing.

high-recycled-content Products of high-recycled content are made mostly with materials that have already been used.

Home Energy Analysis A Home Energy Analysis considers possible measures that can be taken to improve a home’s energy efficiency based on certain criteria.

Home Performance Audit Home Performance Audits are conducted to assess the energy efficiency of a home and evaluate possible energy saving measures.

home-run piping system Home-run or manifold plumbing systems utilize both PEX piping and a manifold. The system is characterized by direct lines from the manifold to any fixtures that reduce the amount of water needed and provides hot water faster.

house wrap House wrap, typically made of polyethylene, is a breathable material used to prevent moisture and wind from entering the home.

IICRC S500 Guidelines The Institute of Inspection, Cleaning and Restoration is an independent, non-profit certification body that sets and promotes standards for the inspection, cleaning and restoration service industry. These guidelines provide specific practical standards for water damage restoration.

infiltration Infiltration is the process by which water seeps through the ground where it may reach a water body or an aquifer.

infrared Infrared radiation is electromagnetic radiation of wavelengths approximately between 0.75 and 1000 mm.

infrared camera Infrared cameras are used to detect thermal variations and may be used in conducting energy efficiency analyses.

infrared imaging Infrared imaging detects thermal variations and may be used in conducting energy efficiency analyses.

Kelvin (K) Kelvin is a universally accepted base unit used to measure temperature. One degree in Celsius is equivalent to one degree in Kelvin. Water freezes at zero degrees Celsius, which is approximately 273.16 Kelvin.

latent cooling load The latent cooling load of an HVAC system is the amount of heat energy produced by moisture from indoor and outdoor sources that needs to be removed from a home in order to maintain a constant temperature.

Light-Emitting Diode (LED) Light-Emitting Diodes are electronic light sources that use less energy than incandescent bulbs or compact fluorescent lamps.

load calculations Load calculations are formulas used to derive the heating, cooling, or electrical loads of a system.

louver(s) Louvers are vertical slats on a window, blind, or shutter that are angled in such away to allow in light and air while providing a shield from rain, direct sunlight, and noise.

low-E Low-E or Low-Emissivity glazings are metal or metal oxide coatings applied to windows to reduce heat flow.

low-VOC Low-VOC products contain smaller amounts of volatile organic compounds (VOCs) that can offgas chemicals and cause air pollution.

manometer Manometers are instruments used to measure pressure.

Microload home The New Jersey Clean Energy Program defines “microload” as a “customized high performance level at or approaching Net-Zero Energy.” While a regular home built to code would receive a Home Energy Rating System (HERS) score of 100; a Microload home would be built to use 50% less energy and would receive a HERS score of 45 or less. Microload homes are eligible for incentives under Tier 3 of the New Jersey Energy Star Home Program.

Modified Energy Factor (MEF) is a combination of Energy Factor and Remaining Moisture Content (RMC). MEF measures energy consumption of the total laundry cycle (washing and drying). It indicates how many cubic feet of laundry can be washed and dried with one kWh of electricity; the higher the number, the greater the efficiency.

moisture meter Moisture meters are devices used to measure the amount of water in a given substance that help determine if it is ready to use.
mold amplification sites Mold amplification sites are locations where mold has built up over time. Typical sites of indoor mold buildup are damp cellulosic materials (e.g., wallboard paper, wallpaper, carpet backing, damp papers); debris in ventilation ducts, in carpets, or in mattresses or upholstered furniture; poorly maintained humidifiers; insulation on which organic film has accumulated; constantly humid painted, caulked or plastic surfaces (e.g., windowsills, shower stalls, cold air return vents); and potted plant soils.

National Air Duct Cleaners Association (NADCA) The National Air Duct Cleaners Association (NADCA) was formed in 1989 as a non-profit association of companies engaged in the cleaning of HVAC systems. Its mission is to promote source removal as the only acceptable method of cleaning and to establish industry standards for the association.

National Fenestration Rating Council (NFRC) The National Fenestration Rating Council (NFRC) is a non-profit organization that administers the only uniform, independent rating and labeling system for the energy performance of windows, doors, skylights, and attachment products.

natural ventilation Natural ventilation systems utilize pressure differences caused by wind or the buoyancy effect (created by differences in temperature or humidity) to circulate fresh air through buildings.

non-CFC sealant Non-CFC sealants do not contain the ozone depleting chemicals chlorofluorocarbons (CFCs).

non-combustible Non-combustible materials are incapable of burning.

optimal load calculations The optimal load of an HVAC system can be calculated to determine the amount of energy required for it to operate the most efficiently.

out-gas/off-gas Out gassing or off-gassing is the evaporation of chemical materials that may be hazardous.

over-sizing Over-sized ducting of HVAC systems may lead reduced indoor air quality and an imbalance of air flow distribution.

Pascal The Pascal is the standard unit of the measure of pressure equal to one Newton/square meter.

passive solar Passive solar home design considers the materials and arrangements of windows, walls, and floors to utilize solar energy for heating in the winter and reduce solar heat gain in the summer.

passive solar design Passive solar home design considers the materials and arrangements of windows, walls, and floors to utilize solar energy for heating in the winter and reduce solar heat gain in the summer.

petroleum-based Petroleum-based products are made from the raw natural resource petroleum, such as oil and natural gas.

phantom load The phantom load refers to the electricity being used by an appliance when it is turned off but still plugged into an outlet.

phenol formaldehyde Phenol Formaldehyde (PF) is commonly used in polymer resins as a safer alternative in pressed-wood materials, off-gassing less formaldehyde than products that use Urea Formaldehyde (UF).

plenum Plenums are boxes made of sheet metal that connect to the outlet of an air handler or furnace where to which other ductwork can attach

plumbing chase A hollow wall area accommodating piping used for drain waste or vent in plumbing systems.

polyisocyanurate Polyisocyanurate is a plastic consisting of closed-cell foam that contains a low-conductivity gas (usually hydrofluorocarbons or HCFC) in its cells. It has a high thermal resistance and is used as insulation that is available as a liquid, sprayed foam, or foam board.

polystyrene Polystyrene is a plastic foam that comes in extruded or expanded forms that are used in various building applications for their insulating properties.

post-consumer recycled content Post-consumer recycled products consist of materials that were previously used by consumers.

pre-primed Pre-primed materials are already prepared with a primer allowing for the application of other products, oftentimes paint.

programmable thermostat Programmable thermostats are devices used to control a home's heating/cooling system that can be set to turn off when no one is home and then back on when the home will be occupied to reduce the cooling load.

R-Value The R-value of a material indicates its resistance to heat transfer.

radiant barrier Radiant barriers are installed in homes to reduce summer heat gain and winter heat loss, and hence to reduce home heating and cooling energy usage. All radiant barriers have at least one reflective (or low emissivity) surface, usually a sheet or coating of aluminum.

rainscreen Rainscreens are used to reduce the exposure of exterior walls to precipitation preventing moisture intrusion and the decay of materials. Every rainscreen consists of vented or porous cladding, an air cavity, a drainage layer on support wall, and a rigid, water-resistant, airtight support wall.

reconstituted wood fiber Reconstituted wood fiber materials use chipped or stranded small-diameter trees as their wood source. This material is then bound together into forms suitable for use in construction.

recycled content Products with recycled content are made from materials that have already been used in another product.

recycled paper cellulose Recycled paper cellulose is an environmentally-friendly insulation alternative made of waste paper.

refrigerant A refrigerant is a compound used in a heat cycle that undergoes a phase change from a gas to a liquid and back used in refrigerators/freezers, air conditioners, and other appliances.

refrigerant charge Refrigerant charge refers to the quantity of refrigerant in a refrigerant system.
**return air duct registers** Registers are vent covers that are typically used on forced air ducts. They have a pre-attached damper or set of louvers to help control airflow.

**return duct** Return ducts prevent the pressurization of closed rooms from supply air by allowing air to flow black to the central return grille.

**return grille** Return grilles are grates used to cover the ends of return ducts.

**rim joist** Rim joists are the boards that cap the ends of the floor system.

**roof overhangs** Roof overhangs are an element of passive solar home design used to shade buildings that may be adjustable, removable, or fixed.

**R-Value** The R-value of a material indicates its resistance to heat transfer. A higher R-value is better than a low R-value.

**sash** Window sashes consist of the moving section(s) of a window.

**Seasonal Energy Efficiency Ratio (SEER)** The seasonal energy efficiency ratio measures the efficiency of a central cooling system over an entire season by comparing the number of BTUs produced to watt-hours consumed.

**sensible cooling load** The sensible cooling load of a home refers to heat gain from the collective impact of conduction, convection, the exterior, people, and appliances.

**sheathing** Sheathing refers to a building material that is used to cover exterior wall framing or roof trusses.

**shutters** Shutters are moveable wooden or metal coverings that, when closed, keep sunlight out. They can be either solid or slatted, with fixed or adjustable slats. Rolling shutters have a series of horizontal slats that run down along a track.

**single-package models** Single-package model HVAC systems have all of their components, including evaporators, cooling coils, compressors, and condensers, contained within one unit.

**single-pane window** Single-paned windows have only one piece of glass separating the interior and exterior of a home. Double-pane windows are considered to be much more energy-efficient.

**six-sided containment** Six-Sided Containment refers to the insulating of all six sides of frame wall cavities in unconditioned, concealed spaces.

**smoke pencil** Smoke pencils detect air pressure differences between two spaces by emitting smoke that leaks through any cracks or openings.

**soffit vent(s)** Soffit vents are applied to the underside of a construction element and are perforated for intake ventilation.

**Solar Heat Gain Coefficient (SHGC)** The Solar Heat Gain Coefficient is the fraction of incidental solar radiation admitted through a window.

**Solar Renewable Energy Certificate (SREC)** SREC stands for Solar Renewable Energy Certificate and is a tradable certificate that represents all the clean energy benefits of electricity generated from a solar electric system. Each time a solar electric system generates 1000 kWh (1 MWh) of electricity, an SREC is issued which can then be sold or traded separately from the power.

**solar screen(s)** Solar screens are mounted to the exterior of windows to reduce sunlight transmittance and prevent heat transfer.

**solar tube(s)** Solar tubes consist of a clear dome that collects sunlight into a highly polished and reflective tube that reflects the light down to a diffuser on the ceiling. They are sufficient to light a small room, hallway, or staircase.

**solar water heating** Solar water heaters or domestic hot water systems utilize storage tanks and solar collectors to provide hot water for a home, saving both energy and money.

**split systems** Split HVAC systems have their components, including evaporators, cooling coils, compressors, and condensers, located inside and outside of a building.

**spray polyurethane** Spray polyurethane foam (SPF) is a plastic insulation that expands after being installed as a liquid.

**stack ventilation** Passive stack ventilation are devices known for extracting warm air from the upper regions of a room or building, with incoming air being admitted via inlets lower down in the room or building. In winter, such incoming air will need to be heated for the comfort of occupants and this is wasteful.

**storm door** Storm doors consisting of a combination of glass and screens can be used to increase the energy efficiency of an exterior doorway.

**storm window** Storm windows are pieces of glass or plastic mounted to the interior or exterior of an existing window that serve to reduce the amount of airflow in and out of a home, reducing heating and cooling loads.

**supply air duct registers** Registers are vent covers that are typically used on forced air ducts. They have a pre-attached damper or set of louvers to help control airflow.

**supply duct(s)** Supply ducts made of formed sheet metal deliver air to interior spaces from an HVAC system.

**supply register** Registers are vent covers that are typically used on forced air ducts. They have a pre-attached damper or set of louvers to help control airflow.

**task lighting** Task lighting, often described as “cool” lighting, produces higher contrasts that are better for seeing. Task lighting sources emit temperatures between 3600-5500K.

**thermal bridging** Thermal bridging occurs when high thermal conductivity materials such as steel and concrete create pathways that bypass thermal insulation resulting in heat loss.

**Thermal Bypass Checklist (TBC)** The Thermal Bypass Checklist is a comprehensive list of building details where thermal bypass, or the movement of heat around or through insulation, frequently
occurs due to missing air barriers or gaps between the air barrier and insulation.

**thermal bypass inspection** The Energy Star® Thermal Bypass Checklist is a comprehensive visual inspection of building details where thermal bypass, or the movement of heat around or through insulation, frequently occurs due to missing air barriers or gaps between the air barriers and the insulation.

**transom** Transoms are the windows above doors that serve to allow in sunlight and release warm air.

**U-Factor** The U-factor of a window assembly indicates its rate of heat loss.

**Ultraviolet (UV) light** Ultra-violet light (UV) is defined as electromagnetic radiation in the spectral region between 180 and 400 nanometers. Prolonged exposure to UV light can result in sunburns, skin cancer, and the fading of certain materials.

**unconditioned spaces** Unconditioned or unfinished spaces including attics and crawlspaces can provide a variety of energy saving opportunities.

**urban heat island effect** The heat island effect occurs in urban areas where impermeable roof and pavement temperatures increase during the summer, elevating the air temperature. The increase in air temperature generates a greater demand in energy consumption for cooling systems and promotes the development of smog due to the concentration of air pollutants in urbanized areas. Also, runoff from these heated surfaces reaches waterways where it can increase the water temperature affecting the ecosystem.

**U.S. Green Building Council’s Leadership in Energy and Environmental Design for Homes (LEED-H) certification** LEED for Homes is a rating system that encourages the building of green homes that use less energy, water and natural resources, create less waste, are healthier and more comfortable.

**vermiculite insulation** Vermiculite is a naturally-occurring mineral, favored for its absorbant, lightweight, fire-resistant, odorless characteristics. Pre-1990 vermiculite insulation products are likely to contain some traces of asbestos associated with the mine where the vermiculite was collected.

**Volatile Organic Compounds (VOCs)** Volatile Organic Compounds are off-gassed from certain solid or liquid products and may cause negative health effects when inhaled.

**wall cladding** A wall cladding is a nonstructural material used as the exterior covering for the walls of a building.

**warm-edge spacer** Warm-edge spacers are used to separate panes of glass in insulated windows and conduct less heat than standard aluminum spacers.

**warp** Warping is the distortion or bending of wood due to moisture.

**Water Factor (WF)** Water factor is the number of gallons needed for each cubic foot of laundry. A lower number indicates lower consumption and more efficient use of water.

**water heater blanket** Water heater blankets are used to insulate water heaters with R-values less than 24.

**weatherization** Weatherization involves procedures that protect a building from the elements.

**weatherstripping** Weatherstripping is the sealing of cracks or holes around windows, doors and other openings exposed to the exterior of a building with caulk, foam, rubber strips, or other materials that can be used to reduce airflow between the interior and the exterior.

**whole house fan** Whole house fans located on attic floors ventilate warm air from interior spaces to the outside while depressurizing the home to draw in cool air from open windows.

**window glazing** Window glazings are compounds applied to glass to reduce the amount of heat transfer between the interior and the exterior of a building and/or the ultra-violet (UV) light passing that passes through it.

**wind-washing** Wind-washing refers to the movement of air caused by wind entering through building enclosures, usually at the corners and roof eaves, that can have a major impact on its thermal efficiency and moisture control.

**zone controller** A zone controller connects multiple thermostats to a single HVAC system.

**zoning** HVAC zoning strategically divides a building into zones where each has its own thermostat for independent temperature control.
Transforming the conventional lawn into green outdoor living space complements the home and connects it with nature. New Jersey, with long summer days and cool autumn evenings, provides a perfect environment for outdoor living. As the primary connection to our natural surroundings, yards function as a beautiful, livable extension of the home. Whether planning your own outdoor project or hiring a professional, there are dozens of ways to implement renewable products, conserve resources, promote biodiversity and wildlife habitat, and reduce home heating, cooling, and water usage.
Outdoor Living and Landscaping

How to Use the Guidelines

Health and Safety
- HS1 - Nuisance and Toxic Dust Control
- HS2 - Cautious Materials - Asbestos & Lead
- HS3 - Mold
- HS4 - Radon

Green Home Maintenance and Housekeeping

General Design and Construction
- Design to support connection with nature [SS15]

Site
- Minimize site disturbance [SS29]
- Conduct a soil test
- Start a compost pile
- Landscape for passive heating and cooling [SS30-31/36]
- Minimize impervious surfaces [SS32]
- Replace lawn with turf grass or groundcover [SS34]
- Provide wildlife habitat [SS35]
- Provide for edible plants in the landscape design [SS37]
- Utilize Integrated Pest Management [SS38]
- Provide rainwater collection system [WE40]

Outdoor Structures
- Use eco-friendly patio/decking materials [MR111-113]
- Properly detail between deck and house [IDP28]
- Plan projects for easy clean-up and disposal [IEQ162]
- Create a roof garden
- Choose eco-friendly pool/hot tub options [EA97]

Lighting and Electrical
- Use efficient lighting/minimize light pollution [EA88-89]

Furniture and Fittings
- Choose eco-friendly furniture/accessories [MR154]

Case Studies

Green Products and Services

Glossary of Terms
How to Use the Guidelines

Organization of the Guidelines

The Guidelines are organized into chapters by major project type: Kitchen, Bath and Living Spaces, Finished Basement and Major Addition, Weatherization and Energy, and Outdoor Living and Landscaping.

Each chapter includes the following:

• How to Use the Guidelines
• Health and Safety
• Green Home Maintenance and Housekeeping
• Best Practice Strategies
• Resources and References
• Case Studies
• Green Products and Services
• Glossary of Terms

Getting the Most from the Strategy Write-ups

The Guidelines provide information on best practice strategies for each project type. These strategy write-ups are organized by building system and follow the order of the 2008 REGREEN Residential Remodeling Guidelines (i.e., IDP2), which are incorporated with permission. Figure 1 describes the information available.

**Figure 1**

A Home Performance Audit identifies energy upgrades for cost savings. Diagnostic tests examine the whole house and look at the interactions between all systems in a home: air leakage, insulation, combustion appliances, heating and cooling systems, and ventilation. Several free online energy audit tools are available for homeowners. The NJ Office of Clean Energy’s Home Energy Analysis Tool offers specific recommendations based on the age of the home; average energy usage, the types of appliances, and other criteria. It is available on the NJ Office of Clean Energy website: www.njcleanenergy.org.

**Title and REGREEN Strategy ID** – The strategies in the REGREEN Residential Remodeling Guidelines 2008 inspired most of the strategies in these Guidelines. Where appropriate, the strategy references the related REGREEN strategy ID.

**Shopping Cart** – The cart denotes entries in the Green Product and Service Guide located in the back of each project chapter.

**Strategy Description** – This write-up provides an overview of each strategy and its environmental benefits.

**Glossary Term** – Acronyms and green building terms are highlighted in bold and defined in a glossary at the back of each chapter.
**Call-out Boxes** - The call–out boxes in Figure 2 highlight information of special importance. These include the following types of information:

- **Tips** - useful hints or practical facts for accomplishing a strategy
- **Incentive** - sources of financial assistance
- **New Jersey Bio-Region** - New Jersey has 5 bio-regions, each with unique elements and environmental features to consider when remodeling
- **Building Age** - a home’s age can inform needed repairs and call out special circumstances
- **Caution** - on occasion, there are hazards associated, so items are called out for safety reasons

**Hazard Symbol** - Symbols were developed to advise users of certain health and safety threats related to specific strategies. The symbols, which appear below, reference the guidance on Health and Safety located at the beginning of each section.

- **HS1 – Nuisance and Toxic Dust Control**
- **HS2 – Hazardous Materials - Asbestos & Lead**
- **HS3 – Mold**
- **HS4 – Radon**

**Web Link** - When viewing this document electronically, the websites will hyperlink, however, occasionally website links change. In most cases, the site provides a seamless link to the new address. If this is not the case, users may need to copy and paste the link into the browser address bar. At the time of publication the hyperlinks in this report were all functional.

**Scorecard** - The scorecard, Figure 3, provides a snapshot of the environmental benefits, initial costs, and difficulty levels associated with a particular strategy. Both qualitative and quantitative information was used to assign scores to each strategy.

It is divided into two parts: 1) Benefits and 2) Feasibility.

**Graphic icons were developed for each impact category.**

**BENEFIT Key**

- 1 icon = low benefit, 2 icons = medium benefit, 3 icons = high benefit

**FEASIBILITY Key**

- $ = low initial cost, $$ = medium initial cost, $$$ = high initial cost
- \( \tt \) = low difficulty level, \( \tt\tt \) = medium difficulty level, \( \tt\tt\tt \) = high difficulty

The icons above have been developed to graphically describe the ratings that follow.

**BENEFITS**

**Energy Savings**

To help meet its greenhouse gas reduction responsibility, in 2007 New Jersey passed carbon dioxide (CO₂) reduction goals, i.e., achieve 1990 emission levels by 2020, followed by a further reduction of emissions to 80 percent below 2006 levels by 2050. The state has also established renewable energy and energy efficiency targets. Green remodeling strategies utilize renewable energy sources such as solar, geothermal, and wind to net a lower CO₂ footprint.
Water Savings

Water conservation reduces water use both inside and outside the home. Within the home this may include low-flow fixtures. Outside the home this may refer to using native plants that have lower watering requirements or rain barrels to collect rainwater for reuse on the lawn and garden. Water management includes providing proper moisture control at footings, slab perimeter, and foundation walls as well as using porous paving materials to encourage stormwater recharge for reduced runoff.

Air Quality

Americans spend up to 90 percent of their time indoors where air quality can be more polluted than outdoors. Pollutants range from allergens such as mold, mildew, fungus, and dust mites to toxins, such as asbestos, and volatile organic compounds like formaldehyde and benzene found in building materials and a number of household items including pressed-wood furniture, computer ink, carpeting, and conventional household cleaners and cosmetics.

Resource Conservation

Resource conservation means using materials that are durable and easy to maintain with low embodied energy (the energy used in resource extraction, manufacturing, shipping). These come from renewable sources or are produced from waste, recycled materials, or salvaged from other uses. Avoiding building materials that deplete natural resources, such as old-growth timber, and materials made from toxic or hazardous substances improves nature’s ability to provide goods and services.

FEASIBILITY

$ Initial Cost

Cost is always a consideration for remodeling projects. Evaluating the cost of a recommended green remodeling strategy provides homeowners with a better sense of the relative costs and benefits of each recommended measure.

Costs come in two forms, so it is important to consider both in assessing feasibility. The first reflects initial costs of the strategy compared to conventional practices. A second consideration to make is the pay-back period or life-cycle cost. The pay-back costs are less obvious and are often project specific, but they can have significant environmental and economic value that factor into the overall cost. For more information on average costs, savings, and payback periods of typical energy efficiency improvements, see the Energy Efficient Rehab Advisor at (www.rehabadvisor.pathnet.org/). For customized results, have an energy professional conduct a thorough energy audit of your home.

Less than $500

$500-$5,000

Greater than $5,000

Difficulty Level

Time is money and expertise is gained over time. Some people may consider a Home Performance Audit strategy in the 'medium' category because although relatively straightforward to act on, it requires experts with custom equipment to prepare an accurate assessment. Implementing the findings from a Home Performance Audit becomes a ‘high’ difficulty category as space heating and cooling systems, ventilation, water heating, appliances, climate and even site factors need to be integrated to assure desired energy improvements across ALL loads and to avoid negative unintended consequences. It is expected that ‘high’ difficulty strategies may also be dangerous for the basic homeowner to undertake.

Easy to Do It Yourself (DIY) - little previous knowledge necessary

Task for an Experienced DIYer or Professional - may require additional effort and higher learning curve than conventional strategy it replaces

Task for an Expert/Certified Professional - high learning curve; new technique; requires specific green knowledge

Health and Safety

Green remodeling poses hazards typical of many other home renovation or remodeling projects because of the age of the homes (given that they are more likely to contain older and use more hazardous materials) and the incentive for green remodeling to replace older or damaged building systems.

New Jersey homeowners considering green remodeling should anticipate potential emissions of hazardous air contaminants during removal of old building materials. The risks associated with improper removal of materials containing asbestos, lead, mold or even fiberglass insulation are minimized by understanding and following the steps listed here prior to initiating work. For complex situations, consider hiring professionals.

General hazard recognition and risk reduction information for the following potential renovation-related risks are contained in this section:

**HS1 – Nuisance and Toxic Dust Control**

**HS2 – Hazardous Materials - Asbestos & Lead**

**HS3 – Mold**

**HS4 – Radon**

**HS1 – Nuisance and Toxic Dust Control**

Construction projects involving demolition of existing sheetrock, plaster, wood, brick or concrete products in ceilings, walls or floors of a home will release dust as these materials are ripped, sanded, ground, pulverized or crushed. Control of dust emissions during the pouring of solids or from transferring of small particles is controlled in industrial facilities. Homeowners planning renovation projects should also consider steps to minimize the release and maximize control of dust in the environment. These nuisance dusts, when released from the point of origin into the air of the home, tend to remain suspended in the air for very long periods of time, and as such, will be transported with air currents caused by open doors, cracks around and beneath doorways, forced air heating and cooling ductwork, and even by the air currents caused by persons walking in and out of dusty areas, to other areas of the home. At a minimum, allowing the uncontrolled release of nuisance dusts from any demolition project, as well as those created from sawing, sanding, or grinding of newly constructed materials (e.g., sheetrock, spackling, wood dust etc.) presents unnecessary and difficult dust cleanup demands for affected living spaces. At their worst, susceptible occupants of homes where uncontrolled nuisance dusts are allowed to escape into adjacent living spaces may temporarily experience eye, nose, or throat irritation. Asthmatics may experience adverse respiratory distress when exposed to high levels of nuisance dust particles.

There are several simple steps to minimize potential hazards of nuisance dust during remodeling.

1. Remove unnecessary porous and non-porous materials (e.g., draperies, bedding, upholstered furniture, children's toys, clothing, etc.) from the project area.
2. Seal the project area from the remainder of the home using polyethylene sheeting at doorways and at inlets to any forced air supply or return registers within the project space.
3. Consider installing HEPA filtered air scrubbers in the project area and discharging the exhaust air through an adjacent window using a tight fitting flexible duct through a sealed window opening (consider surrounding security requirements). Use a lightweight section of facial tissue at the doorways to confirm that air pressure is moving from the clean adjacent living space and into the project area (not the other direction) so that air leaks from the clean home into the dirty renovation area. This will reduce any potential for dusts from the renovation area to enter the adjacent areas of the home.
4. Periodically during the work session and after every work session, HEPA vacuum the renovation area following renovations to remove accumulated surface dust, without re-suspending it into the air.
HS2 – Hazardous Materials - Asbestos & Lead

When removing old building materials, know that they contain hazardous materials, which while intact present little to zero risk to occupants, but when removing can create airborne emissions and increase health and safety risks. This is especially true of asbestos and lead, and, possibly to a lesser extent, fiberglass. Removal of asbestos, lead or fiberglass needs to be planned and conducted with care to minimize exposures to airborne dust from these materials.

Asbestos

Asbestos is a mineral that has been mined in the U.S. since the early 1900’s. Its superior heat resistance properties, combined with its lightweight, high-tensile strength, and non-corrosive qualities, made it an ideal building material for buildings constructed between 1940 and the late 1980’s. Asbestos was banned as a building material in the U.S. after scientists concluded studies linking long-term occupational exposures to damaging respiratory health including asbestosis (scarring of the lung), lung cancer, and mesothelioma (cancer of the lining of the lung). Because intact asbestos presents no increased health risk, there is no requirement for removing it from existing homes. However, when it is disrupted, pulverized or suspended in air, the potential for inhalation of asbestos fibers increases risks of exposure. While health effects develop only after decades of long-term occupational or environmental exposure, homeowners should take particular care to prevent unintentional release of asbestos into the air of their homes during green remodeling efforts so that children and others are not exposed.

Asbestos is commonly found in older homes (constructed between 1940 and the late 1980’s) in the following building materials:

- Pipe and boiler insulation
- Sprayed on fireproofing insulation
- Acoustical tiles and wall coverings
- Floor tiles
- Roof shingles
- Siding shingles

There is no requirement that homeowners remove asbestos-containing materials from homes. However, if removal is part of a green building remodeling project, material should be tested by a New Jersey licensed asbestos control monitor, and if determined to contain asbestos, be removed by a New Jersey licensed asbestos contractor. The number of the state program to contact for assistance in identifying qualified personnel to assist homeowners to safely address any possible asbestos concerns is (609) 292-7837. General information about asbestos and its proper management and disposal can be found at the Department of Health website: www.state.nj.us/health/iep/asbestos.shtml and the Department of Environmental website: www.nj.gov/dep/dshw/rrtp/asbestos.htm.

Lead

Lead was in residential paints prior to 1978. It was banned after that time due to the significant health affects to children inhaling or consuming dusts from lead-based paints. Because of the hazards posed by dusts and chips of lead-painted surfaces, any remodeling or renovation which impacts painted surfaces of homes constructed prior to 1978 needs to be inspected by a New Jersey licensed lead inspector. If lead paint is identified, it should be safely removed by a state of New Jersey licensed contractor. They can safely remove lead-based paint and conduct follow-up surface lead testing to confirm that the removal was successful. Information on lead-based paint and qualifications for lead inspectors and contractors can be found at: www.state.NJ.us/health/iep/documents/pb_advisory_bulletin.pdf.

Contact the New Jersey Department of Health and Senior Services at (609) 292-7837 with any questions.

Fiberglass

Fiberglass insulation is a manufactured glass-wool-like material used as an insulation and sound absorption material in homes, schools, automobiles and consumer products since the 1970’s. Fiberglass insulation can be safely installed if handled properly; any prolonged skin, eye or respiratory contact with fiberglass can cause temporary irritation. During renovation, wear loose fitting clothing and gloves to reduce skin contact, eye glasses or goggles to reduce eye exposure, and N95 disposable respirators (available from any home improvement store) if high levels of fiberglass dust are expected during removal or installation. More information on fiberglass safety precautions and handling recommendations can be found at the American Lung Association website at: www.lungusa.org/site/pp.asp?c=dvLUK9O0E&b=35439 or call the American Lung Association in New Jersey at (908) 687-9340.
HS3 – Mold

Mold contamination of building materials is not limited to older homes. Homes of any age can develop mold if moisture from leaky pipes, roofs, foundations, accumulates in the presence of dust, wood, paper or other cellulose-containing materials at normal room temperatures or high relative humidity (76 percent) for as little as 48 hours. Standing moisture around building materials such as wallboard, carpets, insulation, wood or other cellulose containing materials can cause mold. Many mold spores are known human allergens and produce toxins which may cause irritation or central nervous system effects. Because of vast differences in susceptibility, or if individual health impacts related to elevated mold spore exposure are of concern, consult a trained and experienced occupational/environmental health physician.

In addition to the above, mold damage can occur if flooding from faucets, showers, toilets (above the trap), is not completely dried within 48 hours of the incident. Floods from dirty water sources such as washing machines, dishwashers or sewers may contain high levels of bacteria, viruses, and protozoa which, along with potential mold growth, present additional risks.

If mold amplification sites occur, remove the affected material using methods that prevents unintentional dispersal of mold spores and the source of moisture intrusion. The U.S. Environmental Protection Agency indicates that small areas of mold growth (less than 10 square feet) can be cleaned or removed by homeowners themselves using precautions to prevent exposure and reduce spread of spores to adjacent areas. When mold contaminated areas exceed 10 square feet, special precautions including erecting containment barriers and the use of specialized HEPA vacuum devices should be used by trained professionals. When mold contamination occurs in excess of 100 square feet, professionals need to clean using full containment of the area (see www.epa.gov/mold/moldguide.html).

If mold growth from dirty water floods occurs, take special precautions to prevent skin, eye, oral and inhalation contact, and hire trained professionals to clean up in accordance with U.S. EPA: www.epa.gov/iaq/flood/index.html and IICRC S500 guidelines

Homeowners should anticipate that the amount of mold contamination shown on the outside of a piece of drywall or paneling may be less than the amount that will be exposed when wall cavities are opened up. If there is any doubt, consider hiring a professional Certified Industrial Hygienist (CIH) to evaluate the extent of damage before attempting to remove contaminated building materials yourself.

HS4 – Radon

Radon is a radioactive gas that comes from the natural decay of uranium in the ground. It is odorless, tasteless and invisible, and can only be detected through specialized tests. Radon enters homes through openings such as cracks and joints in the foundation, sump pits and openings around pipes. The home traps radon inside and it can build up to high levels.

Radon is the second leading cause of lung cancer in the United States, resulting in 15,000 to 22,000 deaths annually. It is the leading cause of lung cancer for non-smokers.

Radon concentrations can vary from house to house. The radon concentration in a home depends on a number of factors, including the amount of uranium present in the soil, the permeability of the soil, the number of openings in the foundation and air pressure differentials. Any home can have a radon problem, regardless of whether it is old or new, well sealed or drafty, or with or without a basement.

The New Jersey Department of Environmental Protection recommends radon testing for all homes in New Jersey. If the radon concentration is 4 pCi/L or higher, a radon mitigation system is recommended. There is no safe level of radon since lung cancer can result from very low exposures to radon, however, the risk decreases as the radon concentration decreases. If the radon concentration is less than 4 pCi/L, a mitigation company can be consulted to determine whether the radon level can be brought down still further. Radon levels have been brought to less than 1 pCi/L in sixty percent of the homes mitigated in New Jersey. Mitigation systems can also help reduce the potential for accumulation of volatile organic compounds that may be released from soil water vapor in areas where ground water contamination is an issue.

Radon test kits are commercially available at most home improvement stores, however, test conditions and locations may make data interpretation difficult or inaccurate. Carefully follow the kit directions to ensure proper use and confidence in the results. The New Jersey Department of Environmental Protection has issued licensing requirements for radon testing firms, and has a list of qualified professionals to perform radon testing and mitigation, see www.njradon.org.

Green Home Maintenance and Housekeeping

Introduction

Your home is one of the biggest investments of your life. Can 'going green' protect your investment and make it safer, more enjoyable and save you money? Yes.

This guide to Green Home Maintenance and Housekeeping practices will improve the health, comfort and environment for your family, and save you money, most directly by reducing your utility bills. The guide’s focus on 'Energy' savings, improvements to 'Indoor Air Quality', effective and efficient 'Household Waste Management' and conserving 'Water' all add measurable benefits to you and high return on your investment. Routine checks and repairs will ensure your home’s appearance and proper function. By following these recommendations, you will also prevent more expensive damage from occurring.

Outdoor Living and Landscaping

Smart decisions about lawn maintenance and landscaping techniques improve water quality and local habitat. Environmentally-responsible landscaping increases native plant diversity, and reduces stormwater runoff that deposits sediment and pollutants into local rivers and streams.

1. Lawn and landscape care.
   - Perform a soil test to determine pH and nutrient availability (test for lead near highways and near old buildings).
   - Evaluate site conditions for sunlight, drainage and space requirements for plants.
   - Improve poor soil conditions with organic amendments or quality topsoil. Adjust pH and add nutrients or install soil drainage systems.
   - Select a diversity of plants adapted to site conditions (soil, light, drainage and space), adding native or pest resistant plants to your landscape design.
   - Select low maintenance cultivars and use proper maintenance to reduce unnecessary pesticide and fertilizer use.
   - For lawns, recycle clippings, keep mower at 2 ½ inches, water early morning and de-thatch if thatch reaches more than ½ inch in thickness.
   - Landscape to maximize energy efficiency for heating and cooling of home and surroundings.

2. Tips for yard irrigation.
   - Start a compost pile and use compost in the garden and landscape to improve soil and provide nutrients to plants.
   - Install a rain garden or water collection barrels to reduce the amount of potable water used in your garden and prevent runoff.
   - Drip-irrigate beds. Line gardens with soaker hoses – no sprinklers, no hassle.
   - Use the proper thickness (3 inches) of natural mulches or dark stone (with landscape fabric) around trees and shrubs to conserve moisture and protect roots from excessive hot or cold temperatures.
   - Chip woody waste and tree clippings into mulch for use on-site.
**Design to support connection with nature** [SS15]

Fostering *biophilia* through design beautifies space and promotes health and well-being. Inside the home, use indoor plants to provide visual connections to the outdoors through large well-placed windows. Use and enjoy outdoor spaces through the addition of porches, patios, and decks.1

A great way to better utilize and appreciate a backyard is to treat it as an extension of the home. By creating different spaces in a yard through the use of hedges, fences, or outdoor elements like gazebos or gliders, homeowners can create beautiful spaces that encourage outdoor living. When designing outdoor spaces, consider the intended functions: play areas, meditation areas, outdoor dining areas, etc. It is important to incorporate as many green strategies as possible.

Time spent outdoors can also help reduce energy consumption and household maintenance costs. There are many do-it-yourself guides to creating outdoor living spaces, or invest in a landscape architect or other professional who specializes in designing green outdoor space. Both will add value to the home landscape and add aesthetic benefits for the homeowner.

**Minimize site disturbance** [SS29]

For any home remodeling work, minimizing site disturbance is essential to protect the existing natural environment and prevent soil *erosion*, particularly in New Jersey’s suburban, rural, and shore communities. Before beginning a project, consult with the contractor to develop a comprehensive plan for site protection. The NJDEP has established *Erosion* Control Standards for the state. Check with your New Jersey local conservation district office or the Natural Resource Conservation Service for information about strategies for soil *erosion* prevention (such as silt fencing, mulching, etc.) as well as any applicable laws pertaining to your project. Designate off-site parking and a controlled location for building materials when possible. Smaller sites, such as those found in urban areas, may require additional planning for proper movement of materials on and off of the site.

Carefully provide for protection of trees and vegetation. The *drip line*, a vertical plane going from the perimeter of the crown to the ground, contains the minimum area around a tree that should be undisturbed. However, the shallow root system found in the *topsoil* extends further out from the *drip line*, so preserving extra area beyond the *drip line* minimum is critical. If work requires use of heavy equipment, ask for adequate layers of straw or other material to absorb and distribute the weight to prevent soil compaction. Create *tree wells* for changes in grading around trunks and root systems. Consider establishing a system of incentives and penalties with the contractor for protection of existing trees and shrubs.

Planning for minimizing site disturbance conserves resources by reducing the need for new soil and plantings as well as reducing use of excavation equipment. Protecting and/or transplanting existing vegetation avoids the costs of additional future landscaping. Reducing disturbance and stress on trees and plants will reduce additional watering needs. A pre-construction low impact checklist is provided in the Resource section.

---

1. Tips
   - Mulch around the base of trees will suppress weeds and retain moisture. However, “volcanoes” of mulch built-up around the trunk of a tree will weaken and eventually can kill a tree, so keep mulch to the minimal amount needed.
Conduct a soil test

Soil testing determines the fertility and pH level, and detects levels of metals such as lead in the soil. To best facilitate new plant and garden growth, one should always first conduct a soil test to determine the optimum level of fertilization needed. Excessive fertilization of nutrients and/or lime can be detrimental to plant growth and may lead to contamination of water resources by nitrates, phosphorus, and other chemicals. In addition, understanding the composition of your soil can help to assess the need for any improvements to facilitate water infiltration of stormwater runoff.

Using a sampling probe, trowel, or spade, collect ten to fifteen cores or slices of soil six inches in length from the surface in the area that is being tested. Mix all of the soil samples in a bucket and put two cups into a plastic bag. This sample can then be sent to a soil sample laboratory for testing. Separate samples should also be gathered in areas where different species of plants are grown. Soil sample kits may be purchased from your local Rutgers Cooperative Extension county office, garden center, or online. It is imperative to collect soils following the correct procedures to achieve accurate results. Check the Resources section to find your local Rutgers Cooperative Extension county office. Further information on soil testing can be obtained from these offices.

Start a compost pile

Start a compost pile and use compost in the garden and landscape to improve soil health and provide nutrients to plants. Compost piles contain materials like vegetable scraps, grass clippings, leaves, and sawdust that decompose into natural fertilizer. Compost also helps the soil retain moisture, aiding infiltration and protects roots from excessive hot or cold temperatures.

Homeowners can construct their own compost structures or purchase bins. A compost pile in an inconspicuous part of the yard will eventually decompose, but many prefer bins. Bins not only keep the pile neat and deter animals, they also facilitate the decomposition process. Several New Jersey counties offer tours of different types of compost bins and workshops for composting.

Landscape for passive heating and cooling

Proper placement of trees and landscaping beautifies outdoor space and reduces heating and cooling costs. Taller deciduous trees on the southeast, south and southwest side of a house provide shading from the high summer sun and allow low winter sun to filter into the home. Hardy evergreen trees and shrubs placed at the northeast and northwest corners of the landscape can reduce heating costs by blocking or redirecting cold winter winds over or around the home. On west walls, incorporate trellises, arbors, and planting beds for tall annuals, which provides shading of west-facing windows where summertime heat gain is the biggest problem.
Select site-appropriate plants including native trees that may reduce watering needs once they are established. Any newly planted tree will require watering, but smaller trees will adapt much faster to site conditions. Larger trees will cost more and take longer to establish in the landscape. Evergreens (trees or large shrubs) provide greater protection from wind and noise.

It is always important to consider genetic diversity in the design to minimize potential disease and insect problems. Also see The Tree Guide at www.Arborday.org, listed in the Resources section, for growth rate and crown size information for specific tree species. Check with New Jersey arborists or your county Master Gardeners’ office to choose the right plant for the particular home and lot size. It is important to balance shading with solar access, especially for systems (like solar panels) that require the sun’s energy.

Distance from homes and structures are important considerations. In general, medium to large trees should be placed at least 20 feet away from the house. Trees that will be smaller at maturity can be placed closer to the house, but be mindful of the breadth of the full-grown crown of the tree to maintain both energy and aesthetic value.

Make protection of existing trees and shrubs a priority. When possible, consider transplanting rather than complete removal. If trees or large limbs require pruning, use the tree materials for firewood, mulch, or trellis construction. When transplanting, remember, that they, too, require plenty of water until they are established (generally through at least one season, depending on size).

Minimize impervious surfaces

Stormwater runoff from impervious surfaces can cause flooding, erosion, and surface water contamination. Limiting paved surfaces and providing permeable drainage areas aids natural groundwater infiltration. Porous paving materials, vegetative swales, rain gardens, and other landscape features will improve infiltration.

An overall reduction in paved surfaces prevents runoff, allows for stormwater recharge, and mitigates the heat island effect, reducing home cooling loads. Aiding infiltration of groundwater alleviates possible moisture and mold problems that can impact indoor air quality as well.

Problems associated with water runoff are most prevalent in areas where there is a large percentage of impervious surfaces or in flood prone areas where runoff quickly collects, causing flood hazards. In those areas, or for homes with flat roofs, consider creating a roof garden to absorb stormwater on site. If a home relies on downspouts, direct them away from nonporous surfaces to allow water to infiltrate into the ground without creating runoff.

Rain gardens are depressed areas of the landscape containing various native plant species and are an effective way to reduce runoff and promote infiltration. Directing stormwater to these areas allows the plants and soil to naturally absorb and filter excess water.

The cost to replace, remove or modify existing paved areas can be significant, but it will mitigate hazards and provide various environmental benefits. See the Resources section for information regarding New Jersey’s stormwater regulations, and check with municipal offices for any specific policies.

Replace lawn with turf grass or groundcover

The costs—financially and environmentally—of maintaining a conventional lawn are considerable. Irrigation of landscaped areas accounts for 30 percent of residential water or roughly 7 billion gallons every day. Gas-powered lawnmowers create more air pollution per unit of gasoline than cars.
Groundcovers and garden beds are but a few of the many alternatives to the conventional lawn. Naturalizing with native plants and creating wildlife habitats are gaining popularity in neighborhoods across the country. Where complete removal of lawn area is undesirable, consider replacing the current grass with low-maintenance turfgrass varieties, such as tall fescue and fine fescue that require less water, chemical applications, and less frequent mowing. Rather than a complete overhaul of the yard, consider creating a gradual plan to reduce lawn area, which will help keep cost to a minimum.

Create a certified wildlife habitat

Creating a wildlife habitat can be a fun, rewarding, and educating experience. It allows for greater appreciation of nature, encourages outdoor living, offers a host of ecological benefits and contributes to natural water infiltration and a reduction in lawn area.

Providing a natural habitat for wildlife helps increase local biodiversity and ecosystem stability. It also can facilitate natural pest management, reducing the need for pesticides and other higher cost interventions. In New Jersey specifically, there is a need for providing habitats for honey bees, whose numbers have been in decline. Fostering natural habitats for bees could have a significant impact on local pollination and food production in the state.

In designing a natural wildlife habitat, select a diversity of plants from different families that are adapted to site conditions (soil, light, drainage and space). Select plants that are pest resistant and adapted to site conditions (soil, light, drainage and space). Select plants that are pest resistant and whenever possible use native plants in the design. Incorporate sources of food, water, and shelter: bird houses, feeders, and baths; logs and rocks for ground dwellers; and plenty of shaded areas. It is important to remember that creating a “natural” habitat may not be exactly like the original environment and will take some time for species to adapt to the site.

Incorporate edible plants into landscape design

The Garden State is ideal for growing edible plants at home. Growing even small amounts of fruits or vegetables encourages healthy eating and sustainable lifestyles, protects the environment, and gives gardeners a sense of personal satisfaction.

Food-producing plants require watering, but may require less than a conventional lawn. Incorporating edible plants such as blueberries or raspberries along with ornamentals contributes to overall lawn reduction and less mowing. Growing one’s own food not only saves money at the grocery store, it helps protect the environment by reducing energy use and overall pollution associated with the transportation of food products. Consider using indoor sunspaces or insulated porches for winter growing as well.

There are a wide variety of vegetables, fruits, and herbs that grow well in New Jersey’s climate. Best of all, the seeds and small plants needed to get started are very inexpensive and widely available. Keep in mind that some food-producing plants may need as much water, fertilizer and pesticides as a lawn. For example, vegetables like sweet corn, tomatoes, and melons and fruits such as peaches and apples can be higher maintenance crops. Information on species that grow well in New Jersey, as well as strategies for incorporating edible plants properly into your yard, is available in the Resources section. One may also want to consider protecting their fruits and vegetables from being eaten by animals (i.e., deer, gophers, voles) with a fence. There are also some natural organic repellents that use various smells and tastes to keep pests out of the garden.
Practice Integrated Pest Management

Chemicals from pesticide applications enter our watershed as runoff and infiltrate underground aquifers. They are tracked into our homes by shoes and pets, compromising the safety of our indoor environment. Their toxicity is dangerous to people, children, and wildlife, and they contribute to an overall unhealthy natural world. Therefore, in landscaping, an essential strategy must be to require minimal, if any, chemicals, pesticides, or artificial fertilizers.

Integrated Pest Management includes best practices to minimize environmental impacts by using eco-friendly methods to control pests. IPM’s prevention, monitoring, and control techniques offer an alternative to chemical pesticides. IPM techniques enhance sustainability of vital natural systems, promote insect and disease resistant lawns, trees and shrubs, protecting beneficial insects and wildlife. IPM reduces threats to water quality from chemicals that would otherwise reach our drinking and recreational water resources.

Select low maintenance turf grasses and plant cultivars and use IPM approaches to reduce unnecessary pesticide and fertilizer use.

Provide rainwater collection system

Utilizing a rainwater collection system can be a simple inexpensive way to control runoff and greatly reduce outdoor water use. Add a rain barrel under the roof’s downspout to collect and store rainwater. In the case of significant rainfall events, connect another rain barrel to the system for overflow protection. With the addition of a hose or a spigot, the water is easily used in the yard or garden. Rain barrels can be either homemade or store-bought. See the Resources section for links to step-by-step instructions for constructing your own. More sophisticated systems can store collected rainwater in large underground or above ground tanks, where it is then recycled for irrigation.

This strategy is particularly cost-effective in suburban and rural parts of New Jersey where there is considerable outdoor watering. In all areas, however, rainwater collection is important since it helps alleviate runoff problems.

Check with your local municipality for any restrictions and regulations concerning rainwater collection systems.

Use eco-friendly patio/decking materials

A deck or patio is an important aspect of creating an outdoor living space. Fortunately, consumers have many alternatives for environmentally-responsible materials to create these central features. For wooden decks, consider choosing locally grown cedar or pressure-treated lumber, the best of which is treated with sodium silicate and heat. If this is unavailable, other treatments include copper, borates, and Light Organic Solvent Preservatives (LOSPs). Alternatives to wooden decks are plastic and wood-plastic composite decks. These products are often made from recycled material and generally last longer than wooden decks.
Caution

Cooking on an outdoor grill over plastic deck materials can be a potential fire hazard, as hot coals may quickly ignite these kinds of decks.

Tips

Depending on the decking material, special fasteners may be necessary. For example, copper based preserved lumber is corrosive to steel.

Caution

The REGREEN Guidelines provide instruction on how to properly detail the connection, but if you are not comfortable, consider hiring a professional who can do the work properly.

Tips

An overall reduction in waste materials requires less transport of waste from your home, saving energy and money. Add sawdust from untreated lumber to your compost pile along with leaves and household vegetable waste.

Caution

In older homes, concerns about asbestos and lead paint should be referred to a professional.

NJ Bio-Region

Urban areas in particular can benefit greatly from roof gardens, as they generally contain more flat roof area and less green space at the ground level.

Caution

Do not underestimate the combined weight of soil, plants, and even fruits or vegetables; all roofs, especially those of older structures, need to be examined carefully for structural soundness before attempting this strategy.

Properly detail between deck and house

Fasten and seal decks properly to prevent structural damage from water flowing into the ledger plate and rim joists of the house. A poor connection will shorten the life of the deck and require replacement or repairs far sooner. Carefully detailed connections seal water away from the structure of the house, which also can help protect indoor air from the mold and mildew problems associated with moisture.

Correctly connected decks are especially important in wet and flood-prone and coastal regions of New Jersey, as well as on older homes where age could contribute to structural concerns. A well-constructed connection means a deck will last considerably longer, reducing the need for repair and replacement. This saves money and conserves natural resources.

Plan projects for easy clean-up and disposal

When planning for any outdoor construction, it is important to anticipate sawdust and other waste products and have a strategy for controlling and disposing them properly. Sawdust in particular can be dangerous if it gets into the water system where it can affect water quality for aquatic animals. Proper removal of sawdust prevents it from polluting the water system or from getting indoors and into the air you breathe. When possible, recycling of waste products will save future resources.

The extra planning necessary for proper waste material management is not difficult, but it does require careful consideration.

Create a roof garden

Any flat or gently sloping roof (including those on garages and sheds) can potentially accommodate a green roof. This centuries-old practice has received renewed interest due not only to its aesthetic quality but also the environmental benefits associated with green roofs. Green roofs greatly reduce stormwater runoff, reduce the heating and cooling loads of a building, and help to increase the life span of the roof itself. Moreover, they increase green space and provide a habitat for birds, small animals, and insects.

Green roofs are known by many names - eco-roofs, rooftop gardens, vegetated rooftops, sky gardens, etc. Most green roof systems fall into two categories, extensive and intensive. This
categorization is based on soil depth, but determines a variety of factors including weight, cost, maintenance, plant selection, and function. Not all residential buildings may be structurally designed to handle intensive green roof systems (those that contain several feet of soil and can grow large plants and trees). Extensive green roofs, therefore, may be a more viable option. These roof gardens can contain a wide variety of plants that require minimal care: mosses, lichens, sedums, wildflowers, meadow grasses, etc.. While more limited in the range and size of plant species as a more intensive roof garden, they are cheaper both to create and maintain and provide many of the same environmental benefits.

Another avenue to pursue is a container garden that will allow a homeowner to grow a variety of vegetables and fruits in raised planting beds and plant containers. Growing tomatoes, cucumbers, or peppers in a roof garden is an excellent way for a homeowner to enjoy greater use of the roof.

Choose eco-friendly pool/hot tub options

Swimming pools and hot tubs make great recreational additions to any home, but consume high levels of water and energy. Fortunately there are ways to minimize the environmental damage of pools and hot tubs.

Use a swimming pool cover for a simple, affordable way to prevent evaporation, the biggest source of energy loss in the pool. Prices vary as do styles, so homeowners should expect to spend more on certain alternatives, like a solar cover. The return on investment for a solar pool cover, however, will defray the up-front cost in greatly reduced heating costs. Hot tubs should be well-insulated and have a tight cover to reduce heat loss and evaporation.

Another popular option is to install a solar pool heating system. Swimming pools require simpler solar heating systems than homes due to their design, seasonal use, and lower temperature requirements. The cost for purchasing and installing a solar heating system can be high, but since such a system significantly reduces energy use thus eliminating all future pool heating bills, the payback period improves dramatically. When possible, consider alternatives to high chlorination for swimming pools and hot tubs. Copper/silver electrolysis, ionization, and UV technologies offer alternatives to chemically-treated water. Saltwater pools are also viable alternatives, but may be subject to local prohibitions.

Use efficient lighting/minimize light pollution

In recent decades, nighttime light pollution has become an increasing concern. While many cite safety as the main reason to keep areas lit at night, there are a host of problems associated with outdoor lighting. Not only does it block out the view of the night sky, it negatively impacts sleeping patterns and disturbs the natural cycles of plants and animals. In addition, too much nighttime lighting may actually reduce overall visibility. Excessive use of nighttime lighting puts additional energy cost burdens on both individual owners and to municipal and state governments. Light pollution is a major concern in densely-populated New Jersey, especially in its urban areas; our state’s residents should seek opportunities to reduce their individual contributions to this problem.

Fortunately there are ways to reduce light pollution. Motion sensors provide light only when needed, which cuts overall lighting and saves electricity. Also, full cut-off fixtures limit light above or to the side of the fixture. These features are commonly available and, once installed, do not require daily maintenance. Consider replacing old light fixtures with Energy Star®-rated ones. Choose solar powered lamps as alternatives for lighting along driveways and walkways. These units store energy during the day, are easy to install and do not require any electricity or wiring.

Tips

Since outdoor motion sensor lighting requires lamps that turn on instantaneously, incandescent bulbs are more appropriate than CFLs in those types of fixtures. Advances in LED lighting will make them more affordable than they currently are and a greener option for outdoor lighting.

NJ Bio-Region

In New Jersey, many municipalities and counties (including Eatontown, Hopewell Township, Moorestown, and Hunterdon County) have enacted outdoor lighting ordinances intended to control light pollution. More locations may follow suit as public awareness of the problems associated with light pollution increases. Be sure to check local ordinances for outdoor lighting requirements or restrictions.

Caution

CFLs contain small amounts of mercury. Therefore, they need to be recycled properly. See the Resources section for information on how to clean up a broken CFL.

Outdoor Living and Landscaping 225
Choosing outdoor furniture is difficult since weather degrades many materials. Furniture made from *virgin plastic* and PVC (vinyl) is generally inexpensive but degrades in sunlight, requiring more frequent replacement and creates solid waste problems. Therefore, consider locally-grown cedar products, FSC-certified wood furniture or furniture made from High-Density Polyethylene (HDPE) composite material.

For other outdoor equipment, look for durable products designed to withstand the elements, including stainless steel grills and terra-cotta fire pots. Whenever possible, consider using salvaged wood and other products for furniture or accessories. With a little creativity, salvaged products can make attractive outdoor accessories.

Overview and Scope

This project involved a home converted from stables located on a six-acre property. The homeowners approached Back to Nature in 2002 to help transform the outdoor spaces surrounding the home to be in tune with their organic, nature-loving, and family-oriented lifestyle. The project incorporated several environmentally-conscious strategies, and the outdoor spaces continue to develop as a reflection of the clients' green lifestyle.

Design Approach

The original goal of this project was to create a series of outdoor rooms that would “unfold” in a way similar to the indoor rooms of a home. The project started with a site master plan that evaluated the barriers between indoors and out. Over the next seven years, the landscape architect continued working with the client as the project evolved in the areas of growing organic food, restoring native habitats, integrating alternative energies and stormwater retention practices, promoting a healthy and inviting atmosphere for family and friends, and connecting the homeowners with their land.

Team and Process

An integrated design process has played a value-adding role in realizing the potential of this project. Over the course of this outdoor remodel, stakeholders have included the clients, the landscape architect, architects, contractors from all trades, engineers, arborists, organic consultants, apiary specialists, forest managers, municipal agents, and neighbors.

Finance

Costs are an important consideration for all projects. This venture was no different as costs were woven into the fabric of the project. The project team anticipated and realized both tangible and intangible returns on the investments into this project including a decreased reliance on purchased produce, transportation energy savings and a greatly expanded living space.

Lessons and Trade-offs

The landscape architect points out that there are always surprises in the construction industry; it is a matter of recognizing that fact and anticipating as many of the surprises as you can up front. Having said that, he did not think he would have done anything differently. One thing that this project taught him was that the entire process must be flexible and evolve the same way that the stakeholders and the site do. The world is constantly changing, and so all projects must evolve with it.

“'The most rewarding aspect of this project is the relationships I have found myself in with the clients and the other professionals that have had a stake in this regenerative residence.”

- Michael Fleischacker
List of Green Strategies

Native Restoration
• Converted lawn to birch grove garden, woodland gardens, and native stone terraces
• Removed invasive species and reintroduced native species to woodland ground covers and understory
• Removed stilt grass and lawn from septic field area and reseeded with native prairie mix

Growing organic food and flowers
• Planted peach, pear, and apple trees in orchard
• Created a part-shade herb and vegetable garden with plants selected for their historic medicinal and food value
• Incorporated raised garden beds and a kitchen/cutting garden that expanded significantly the farming capabilities of the property
• Incorporated cold frames to extend the growing seasons and provide a controlled environment for drying fruit, herbs, and vegetables
• Created compost bins from cedar logs, allowing for 100 percent of biodegradable waste to remain on-site and be reintroduced as compost soil in the garden beds
• Built a corn crib-inspired wood shed used to split and store wood harvested from dead or fallen trees, which then are used in wood burning stoves as alternative heating for the residence and ancillary structures
• Created an apiary garden with a beehive that produces fresh honey for a variety of family uses while adding value to the gardens through pollination
• Proposed future projects, including a “green” greenhouse and free range chicken

Other Green Strategies
• Installed low voltage landscape lighting
• Planted edible “living” holiday trees for wildlife habitat and food throughout the winter
• Utilized regional materials and contractors for all aspects of this project.
• Installed an outdoor kitchen
• Proposed photovoltaic array, salt water spa, and solar energy for water heating
he worked closely with the green roof suppliers to make sure all components were correctly installed. Over time, he became very committed to the project and felt a genuine pride and enthusiasm in his contribution.

Finance
Since the actual size of the green roof was relatively small (approximately 250 square feet), the added cost of a green roof was not as much of an issue as it would have been for a larger area. The owner/landscape designer was committed to doing a green roof; the additional cost was not an issue.

The owner is a recent graduate of the NY Botanical Garden in Landscape Design and had many contacts at the school for suppliers of green roof materials. She acquired estimates for building the green roof from several of these established green roof supplier/builder teams prior to actually selecting the supplier and builder. When a builder the owner had previously used said he would come out of retirement and travel up from Florida to do the project, the owners decided it was an offer too good to refuse. The actual cost incurred by purchasing the supplies directly from a green roof supplier and using the owners’ contractor was approximately 10 percent less than working with an established supplier/builder team. The cost of the green roof was approximately 15 percent more than a high quality copper standing seam roof which would have been the alternate choice.

The owner anticipates a lower cost for heating and air conditioning as a result of installing a green roof and having good cross ventilation compared to a more traditional roof. The savings, however, are difficult to quantify since the room has only existed with a green roof and there would be no other comparable experience.

Lessons and Trade-offs
There were no serious surprises with this project. The roof was designed and built in an arched form to match the surrounding landscape. The construction work involved in implementing the roof curve was more than anticipated and added to the complexity of installing the green roof components.

Serious planning was required to determine the plants for the green roof. The site is only sunny for about a third of the day, so sedum plants, which are traditionally used for green roofs and thrive in the hot, dry sun, were not an option. Instead, the landscape designer decided to use a palette of low-maintenance, drought-tolerant, ground cover plants with various leaf textures and flowering times. The plants were installed in late August 2008 and have thrived in the special green roof growing media. It is anticipated that some supplemental watering will be required for the first year or two until the plants are well established. This plant palette also required a media depth of 4 - 5 inches. The structural engineer needed to take into account this additional roof load when specifying the glulam support beams.

In the opinion of the landscape designer and owner, the combination of the aesthetics of a green roof and its ecological advantages make it an obvious solution for anyone who is interested in the environment and has an appreciation of nature.
“I felt the project was a great example of collaboration and synergy between the architects, builder and owner. Each provided their own particular expertise and worked collaboratively with the others, presenting ideas and brainstorming solutions. The final result is terrific.”
- Barbara Geller, owner/landscape designer

List of Green Strategies

Energy Conservation
- Installed green roof to reduce heating and cooling load
- Incorporated cross ventilation into window design to reduce cooling load
- Installed roof overhang to reduce summer heat gain and increase winter passive heat gain from the sun
- Installed radiant floor heating
- Increased roof insulation R-Value by using foam insulation

Water Conservation
- Reduced stormwater runoff by installing green roof

Resource Conservation
- Reused Bucks County field stone from an abandoned stone wall found up the road from new structure

Outdoor Air Quality
- Increased carbon dioxide absorption and oxygen emission from the green roof plant photosynthesis
Green Products and Services

Introduction

The purpose of the Green Products and Services is to help homeowners navigate the market with some helpful tips on what to look for when shopping for a particular green home remodeling project. The Guide is organized by building system and lists the general products and services that pertain to remodeling tasks within that system. It includes features and applicable certifications to look for, as well as web links to more information on that product or service. Each item in the Guide also refers to the related REGREEN strategy IDs.

Please note that the New Jersey Green Home Remodeling Guidelines Version 1.0 do not endorse any particular brand or company. It is not the function of the Green Product and Service Guide to direct the consumer to a specific product, but rather to provide a resource to seek out an appropriate manufacturer or service provider to handle remodeling needs.

With the ever-increasing number of green products and services coming into the home remodeling market, finding the appropriate ones can be a challenge. Some manufacturers market products as “green” when in reality they are only marginally better for the environment or whose green features are neutralized by other aspects of their manufacturing or composition. This phenomenon is referred to as “greenwashing” and calls on consumers to seek out references and ensure the true extent of green value.

Product Certification Programs

That being said, there are several leading green product standards and certification programs that can help consumers identify products that meet predefined green criteria. The leading green product standards and programs include:

- Energy Star® - identifies efficient products that reliably deliver energy savings and environmental benefits
- WaterSense – identifies high performing, water efficient products and practices
- Cradle to Cradle - certifies products based on lifecycle of materials used to construct a product and the overall lifecycle of the product
- GreenGuard® Certification Program - certifies products and processes for their low chemical emissions and low toxicity
- Green Seal® - certifies products and practices for their low toxicity and overall environmental impact
- GreenSpec Directory - a published resource on environmentally preferable products
- Forest Stewardship Council (FSC)- certifies wood products coming from forests managed to meet social economic and ecological needs
- Sustainable Forestry Initiative (SFI) - certifies wood products coming from well-managed forests and responsible procurement practices
- National Fenestration Rating Council® (NFRC) - a non-profit organization that administers the only uniform, independent rating and labeling system for the energy performance of windows, doors, skylights, and attachment products

For more information on various certification programs currently in use by architects and designers see:

- the ecolibrary™matrix - www.thegreenstandard.org/documents/GGNC09_EcoLibCert.pdf
- Gaia Product Profile developed by The Green Standard™ - www.thegreenstandard.org/gaia.html

Two other reputable sources for green products and services are:

- Green Building Advisor that lists products from the GreenSpec Guide to Residential Building Materials www.greenbuildingadvisor.com/
Product Standards for GreenSpec

1. Products Made with Salvaged, Recycled, or Agricultural Waste Content
   a. Salvaged products
   b. Products with post-consumer recycled content
   c. Products with pre-consumer recycled content
   d. Products made with agricultural crop waste material

2. Products That Conserve Natural Resources
   a. Products that reduce material use
   b. Products with exceptional durability or low maintenance requirements
   c. Certified wood products
   d. Rapidly renewable products

3. Products That Avoid Toxic or Other Emissions
   a. Natural or minimally processed products
   b. Alternatives to ozone-depleting substances
   c. Alternatives to hazardous products
   d. Products that reduce or eliminate pesticide treatments
   e. Products that reduce stormwater pollution
   f. Products that reduce impacts from construction or demolition activities
   g. Products that reduce pollution or waste from operations

4. Products That Save Energy or Water
   a. Building components that reduce heating and cooling loads
   b. Equipment that conserves energy and manages loads
   c. Renewable energy and fuel cell equipment
   d. Fixtures and equipment that conserve water

5. Products That Contribute to a Safe, Healthy Built Environment
   a. Products that do not release significant pollutants into the building
   b. Products that block the introduction, development, or spread of indoor contaminants
   c. Products that remove indoor pollutants
   d. Products that warn occupants of health hazards in the building
   e. Products that improve light quality
   f. Products that help noise control
   g. Products that enhance community well-being

aquifer An aquifer is an underground formation of permeable material that contains a substantial quantity of water.

arbor(s) Arbors or pergolas, as they are commonly known, typically consist of a combination of pillars, cross beams, and lattice work upon which vegetation such as vines can be trained and provide shade. Some varieties are attached to existing structures including houses or decks.

asbestos Asbestos is the name given to a number of naturally occurring, fibrous silicate minerals mined for their useful properties such as thermal insulation, chemical and thermal stability, and high tensile strength. Asbestos is commonly used as an acoustic insulator, and in thermal insulation, fire proofing and other building materials. Many products in use today contain asbestos.

biophilia The term biophilia literally means the “love of living things.” It was coined by Edward O. Wilson, an entomologist at Harvard University, to describe his hypothesis that humans have an inherent connection to nature associated with our evolution.

borate(s) Borates are boron-containing, naturally-occurring minerals. Common commercial applications of borates include wood treatment, detergent additive, and plant fertilizer.

combustion appliances Combustion equipment refers to appliances that burn fuels including stoves, water heaters, and clothes dryers. It is important to make sure that these appliances work correctly and are properly ventilated to prevent carbon monoxide, a byproduct of combustion, from entering the home.

Compact Fluorescent Lights (CFLs) Compact fluorescent lights are the miniature fluorescent lights that can screw into standard light fixtures that conventionally use incandescent bulbs. CFLs are more energy-efficient and durable than incandescent bulbs.

companion planting Companion planting can be described as the establishment of two or more plant species in close proximity so that some natural benefit (pest control, higher yield, etc.) is derived.

compost pile A compost pile consists of organic matter including lawn clippings, leaves, and branches that is typically collected in a bin where it can decompose and be added to plant beds improving the soil quality with nutrients.

container garden Containers including planter boxes, wooden barrels, and large flower pots can be filled with soil, be planted, and arranged as an addition to an existing garden or to create a new one where plants wouldn’t otherwise be able to grow in places such as rooftops or patios.

cooling load Cooling load refers to the amount of heat that gets removed by an HVAC system.

copper/silver electrolysis Electrolysis is the process by which an electric current is passed through a substance that causes it to gain or lose electrons.

deciduous tree(s) Deciduous trees are species that shed their leaves for part of the year.

dethatch Dethatching is the removal of dead grass from a lawn.

disposable respirators Disposable respirators or filtering facepieces can be made of cloth or paper and are designed to clean the air as you breathe it to prevent you from inhaling irritating substances.

drip-irrigation Drip, or micro-irrigation, technology uses a network of plastic pipes or soaker hoses to carry a low flow of water under low pressure to plants. Drip irrigation exceeds 90 percent efficiency whereas sprinkler systems are 50 to 70 percent efficient.

dripline The dripline of a tree refers to the area of ground located directly under the circumference of its outermost branches. This area indicates where the tree should be watered as opposed to the base of its trunk where it can develop root rot.

erosion Erosion is the process by which soil and rock are worn away through water, wind, ice and wave transport.

evergreen trees Evergreen trees retain their needles or leaves through the winter and into the next growing season.

fine fescue Fine fescues are grasses chosen for their advantageous IPM qualities such as drought tolerance, low maintenance, texture and color differences, and their performance as natural or unmowed areas.

Forest Stewardship Council (FSC) – Certified Wood The Forest Stewardship Council certifies wood that complies with its standards-disapproving of illegally harvested wood, wood harvested in violation of traditional and civil rights, in forests in which high conservation values (areas particularly worthy of protection) are threatened through management activities, from conversion of natural forests, and from areas where genetically modified trees are planted.

full cut-off fixture Full cut-off light fixtures direct light from outdoor light sources to where it is needed and block excess light that is emitted upwards or sideways reducing light pollution.

garden bed Garden beds are designated areas in a landscape for plants and other natural materials.

genetic diversity Genetic diversity refers to the variety in a gene pool of a species or population.

glazing Window glazings are compounds applied to glass to reduce the amount of heat transfer between the interior and the exterior of a building and/or the ultra-violet (UV) light passing that passes through it.

glulam Glulam is a structural timber product composed of laminated layers of wood. It is generally composed of woods that could otherwise be waste. The laminate strengthens the beams making them good elements for green roofs.

green roof Green roofs are contained vegetative roof coverings that provide a variety of economic, ecological, and aesthetic benefits including reducing the heating/cooling loads of the building, reducing runoff, and producing oxygen among others.

extensive Extensive green roofs are 6 inches or shallower and are frequently designed to satisfy specific engineering and performance goals.

intensive Intensive green roofs may become quite deep and merge into more familiar on-structure plaza landscapes with promenades, lawn, large perennial plants, and trees.
hardy turf grass  Hardy turf grasses are able to grow in a variety of conditions and are low maintenance reducing the need for fertilizers and pesticides.

heat island effect  The heat island effect occurs in densely urbanized areas where impermeable roof and pavement temperatures increase during the summer, elevating the air temperature. This in turn generates a greater demand in energy consumption for cooling systems which concentrates air pollutants and creates smog. Runoff from these heated surfaces reaches waterways where it can increase the water temperature and negatively affect ecosystems.

HEPA filtered air scrubbers  High efficiency particulate air or HEPA air filters are a type of high-efficiency air filter that remove at least 99.97% of airborne particles down to a size of 0.3 micrometers (µm) in diameter.

HEPA vacuum  High efficiency particulate air or HEPA filters are a type of high-efficiency air filter that remove at least 99.97% of airborne particles 0.3 micrometers (µm) in diameter. HEPA filter used in vacuum cleaners trap the fine particles (such as pollen and dust mite feces) which trigger allergy and asthma symptoms.

High-Density Polyethylene (HDPE)  High-density polyethylene (HDPE) is a thermoplastic used to make milk bottles, packaging containers, toys and other products. It is known for its resistance to most chemicals, high impact tensile strength, and insolubility in organic solvents.

Home Performance Audit  Home Performance Audits are conducted to assess the energy efficiency of a home and evaluate possible energy saving measures.

IICRC S500 Guidelines  The Institute of Inspection, Cleaning and Restoration is an independent, non-profit certification body that sets and promotes standards for the inspection, cleaning and restoration service industry. These guidelines provide specific practical standards for water damage restoration.

impervious surface  Impervious surfaces such as concrete and conventional asphalt that do not allow water penetration.

indoor sunspace  Indoor sunspaces provide a buffer between a home’s interior and exterior reducing the exposure of temperature fluctuation and direct sunlight. Made of glass, they may serve as an additional living space where the user can enjoy the natural warmth and light produced by the sun.

infiltration  Infiltration is the process by which water seeps through the ground before reaching a nearby water body or an aquifer.

Integrated Pest Management (IPM)  Integrated Pest Management is an effective and environmentally sensitive form of pest management that utilizes monitoring, prevention, and control techniques.

ionization  Ionization is a treatment where water passes through a metal chamber (usually copper or silver) exposed to a low voltage causing the ions to penetrate the outer membrane of any pathogens in the water and thus kill or render them harmless.

ledger plate  A ledger plate is a strip of wood laid flat across the tops of studding as a support for joists.

Light-Emitting Diode (LED)  Light Emitting Diodes are electronic light sources that use less energy than incandescent bulbs or compact fluorescent lamps.

Light Organic Solvent Preservatives (LOSPs)  Light organic solvent preservatives contain insecticides and sometimes water repellents to protect wood from pests and weather conditions.

light pollution  Light pollution is excessive, unwanted light typically projected upward and/or outward from an artificial light source.

mold amplification sites  Mold amplification sites are locations where mold has built up over time. Typical sites of indoor mold buildup are damp cellulosic materials (e.g., wallboard paper, wallpaper, carpet backing, damp papers); debris in ventilation ducts, in carpets, or in mattresses or upholstered furniture; poorly maintained humidifiers; insulation on which organic film has accumulated; constantly humid painted, caulked or plastic surfaces (e.g., windowsills, shower stalls, cold air return vents); and potted plant soils.

National Fenestration Rating Council (NFRC)  The National Fenestration Rating Council (NFRC) is a non-profit organization that administers the only uniform, independent rating and labeling system for the energy performance of windows, doors, skylights, and attachment products.

native plants/species  Native plants, species or trees that occur in the region in which they evolved.

natural pest management  Natural pest management employs pest control techniques that are environmentally sensitive and effective based on prevention, monitoring, and using the least toxic chemicals possible.

non-porous  Non-porous materials lack any spaces where gasses or liquids can pass through.

organic amendments  An organic soil amendment improves soil’s water retention, permeability, water infiltration, drainage, aeration and structure by adding materials such as wood chips, grass clippings, straw, compost, manure, sawdust and wood ash. Organic is a greener substitute for inorganic amendments that use non-living or synthetic materials.

pH  pH is a measure of the acidity or basicity of a solution. Solutions with a pH less than 7 are said to be acidic and solutions with a pH greater than 7 are said to be basic or alkaline.

planting bed  Planting beds are areas designated in a landscape for planting.

porous  Porous materials have spaces through which gases and/or liquids can pass.

pressure-treated lumber  Pressure-treated lumber undergoes a process where chemical preservatives are infused deeply within. These products are insect and rot resistant and can be found in a variety of forms including boards, posts, and plywood primarily for exterior use.

PVC (vinyl)  Polyvinyl chloride is a plastic commonly used as piping that is capable of off-gassing harmful chemicals.
**Rainwater Collection System** Rainwater collection systems, also known as rainwater catchment systems or rainwater harvesting, employ a system of gutters, pipes, and containers to collect and store rainwater from roofs. Depending on the amount of water collected, it can serve as a primary or supplementary water source for such uses as watering plants. Collecting rainwater reduces runoff and saves resources.

**Rainwater Garden** Rainwater gardens are constructed landscape systems that utilize native plants to collect runoff.

**Rim Joist** Rim joists are the boards that cap the ends of the floor system.

**Roof Garden** Roof gardens are landscape systems constructed on a building’s roof to reduce runoff, decrease heat island effect as well as cooling load in the summer and heating load in the winter, remove air pollutants, and add aesthetic value among other purposes.

**Runoff** Runoff is water that doesn’t infiltrate the ground but instead flows above ground to a water body.

**Single-Pane Window** Single-paned windows have only one piece of glass separating the interior and exterior of a home. Double-pane windows are considered to be much more energy-efficient.

**Solar Cover** Solar covers are used to retain the water temperature in pools and may also serve as a form of protection.

**Solar Pool Heating System** In solar pool heating systems water circulates through a large heat exchange surface, usually located on your roof, and absorbs the sun’s energy. Most solar ‘collectors’ are flat black panels manufactured from high technology plastics which have been designed to resist weather and ultraviolet radiation. These heating systems can also be used for hot tubs.

**Stormwater Recharge** Stormwater recharge is the active restoration of groundwater resources by way of stormwater drainage systems.

**Tall Fescue** Tall fescues are grasses that can grow in cool conditions as a lawn, for erosion control, athletic fields, and other uses.

**Thatch** Thatch is a layer of grass stems, roots, clippings, and debris that settle on the ground and either slowly decompose and/or accumulate over time. Some thatch is healthy for a lawn, but excessive thatch (over 1/2 inch thick) creates a favorable environment for pests and disease, an unfavorable growing environment for grass roots, and can interfere with some lawn care practices.

**Topsoil** Topsoil is the outermost layer of soil primarily composed of organic matter.

**Trellis** Trellises are structures that usually consist of latticework to support vegetation including vines and other creeping plants.

**Ultraviolet (UV) Technologies** Ultraviolet technologies include systems that utilize ultraviolet radiation for purposes such as water treatment.

**Vegetative Infiltration Swale** Vegetative infiltration swales are planted areas intended to catch runoff where it can be filtered and enter the ground.

**Virgin Material** Virgin material is made exclusively with raw materials and contains no recycled content.

**Watershed** Watersheds physically describe the drainage basins of a region including all lands and water bodies that flow into it main waterway.

**Windbreak** Windbreaks are barriers typically consisting of trees, shrubs, crops, fences, and other materials to direct wind flow.

Rutgers Center for Green Building [RCGB]

The Rutgers Center for Green Building is located at the Edward J. Bloustein School of Planning and Public Policy, Rutgers, The State University of New Jersey. The Center forms a common umbrella for existing and proposed initiatives being carried out through separate Centers at the Bloustein School, the School of Environmental and Biological Sciences (formerly Cook College), the School of Engineering and other Rutgers units that are integral to developing and implementing innovative green building strategies.

The Rutgers Center for Green Building has developed capabilities in applied green building research that entail modeling the life cycle cost and environmental impact of buildings, post occupancy study tools including survey research and building operating data analysis, and financial methodologies to better estimate green building value. The Center has produced a series of reports documenting best practices in green building and regularly provides green building training and education modules for a variety of audiences.

The development of the New Jersey Green Home Remodeling Guidelines (NJGHRG) Version 1.0 was funded by the New Jersey Department of Environmental Protection (NJDEP) and the U.S. Environmental Protection Agency (USEPA), who contributed a grant for workshops and other marketing activities.

The Rutgers Center for Green Building developed the guidelines with extensive input and review by an expert advisory group comprised of residential building and remodeling professionals, interior designers, landscape architects, and experts in the field of green building and energy-efficient design.

Printed on recycled chlorine-free paper using non-toxic toners.
